(54) Title: ANTIFREEZE PROTEINS ISOLATED FROM FORAGE GRASSES AND METHODS FOR THEIR USE

(57) Abstract: Isolated polynucleotides encoding antifreeze polypeptides are provided, together with expression vectors and host cells comprising such isolated polynucleotides. Methods for the use of such polynucleotides and polypeptides are also provided.

ANTIFREEZE PROTEINS ISOLATED FROM FORAGE GRASSES
AND METHODS FOR THEIR USE

5 Reference to Related Applications

This application claims priority to U.S. Provisional Patent Application No. 60/409,557 filed September 9, 2002.

Technical Field of the Invention

10 This invention relates to polynucleotides isolated from forage grass tissues, specifically from *Lolium perenne* (perennial ryegrass) and *Festuca arundinacea* (tall fescue), as well as oligonucleotide probes and primers, genetic constructs comprising the polynucleotides, biological materials (including host cells and plants) incorporating the polynucleotides, polypeptides encoded by the polynucleotides, and methods for 15 using the polynucleotides and polypeptides. More particularly, the invention relates to antifreeze polypeptides involved in ice recrystallization pathways, and to polynucleotides encoding such polypeptides that confer freezing tolerance to plants.

Background of the Invention

20 Many organisms that inhabit environments where they are repeatedly exposed to freezing conditions have evolved specific antifreeze proteins (AFPs) that provide both freeze resistance and freeze tolerance (for review see Jia and Davies *Trends in Biochemical Science* 27:101-106, 2002). Significant potential exists to improve the survival of organisms, such as plants, by enhancing the expression of antifreeze proteins 25 or by introducing antifreeze proteins into organisms that are currently freeze-intolerant. Such methods would, for example, extend the range of climates in which forage crops and other commercially useful plants could be produced. Such methodology could also be applied to microorganisms in order to increase survival during recovery from cold temperatures, or may be employed in a similar fashion to improve survivability 30 associated with temperature fluctuations which occur during transportation at low temperatures.

Antifreeze proteins are found in a wide range of organisms including plants, fish, insects and bacteria. Although all AFPs are ice-binding proteins, there is a large variation in structure and amino acid sequence between organisms. For example, the

AFPs from fish are very different from those of plants. Even within different plant species there is little amino acid sequence homology between known AFP proteins, indicating that AFPs have evolved separately in a number of plant species. This structural diversity has made it difficult to identify functional domains in the AFP 5 proteins, as well as to identify residues involved in the ice-protein interaction.

It has been proposed that AFPs bind to ice as a receptor-ligand interaction, with ice and AFPs being the ligand and receptor, respectively, to prevent further growth of the crystals. In certain freeze tolerant organisms, such as plants, the ice forms in the extra-cellular space. At several degrees below the melting point there is a tendency for 10 ice to re-crystallize, with large crystals forming at the expense of smaller ones. These large crystals have the ability to irreparably damage cells. The main role of AFPs is therefore to slow or halt this re-crystallization process. Plant AFPs in particular tend to be good at inhibiting the ice re-crystallization process thereby lessening the damage caused by freezing. This contrasts with AFPs of Antarctic marine fish, which have an 15 additional thermal hysteresis (TH) activity that reduces the freezing temperature of water inside the fish by controlling ice crystal growth.

Plant AFPs have been isolated from rye, perennial ryegrass and carrot. The carrot protein contains leucine-rich repeats and has some similarity with polygalacturonase inhibitor proteins (Worrall *et al.*, *Science* 282:115-117, 1998; 20 Smallwood *et al.*, *Biochem. J.* 340:385-391, 1999). Over-expression of the carrot antifreeze protein in transgenic tobacco plants resulted in accumulation of this AFP in the apoplast. In ice re-crystallization experiments, the carrot protein inhibited the size of ice crystals formed. The TH activity of the carrot AFP was low; between 0.2 to 0.6 °C.

25 The perennial ryegrass AFP is rich in asparagine, valine and glycine residues and shares no sequence homology to the carrot AFP (WO 99/37782, Sidebottom *et al.*, *Nature* 406:256, 2000). The grass AFP has ice re-crystallization activity similar to that observed for the carrot AFP and has a low TH (0.2 – 0.45 °C). A theoretical three-dimensional structure has been developed for the grass AFP protein showing that it has 30 a β-roll conformation (Kuiper *et al.*, *Biophys. J.* 81:3560-3565, 2001). This gives the protein a long flat structure and presents two large flat surfaces for ice-binding. The physico-chemical characteristics of an AFP derived from *Lolium* have recently been investigated (Pudney *et al.*, *Archiv. Biochem. Biophys.* 410:238-245, 2003).

The scope for AFP applications extends from genetically modifying prokaryotic or eukaryotic organisms to produce formerly non-resident AFP proteins, into areas where AFPs are used as additives for cryoprotection. An example of this is molecular biology reagents such as restriction endonucleases, DNA modifying enzymes, DNA 5 polymerases and associated buffers which are sensitive to freeze thaw. Molecular biology reagents which are particularly sensitive to freezing, such as *in vitro* transcription/translation systems could potentially benefit by the presence of AFPs. Whole cells, such as preparations of *Escherichia coli*, yeasts, blood platelets, red blood 10 cells, ova and sperm, in addition to multicellular complexes such as embryos and whole organs, could be protected by the ice restructuring properties of AFPs.

AFPs may also be usefully employed in frozen food products where small crystalline structure is desirable, such as ice cream, and to provide a superior food quality upon thawing of frozen food products such as frozen fruit. For example, International Patent Publication WO 92/22581 describes the use of plant AFPs in 15 controlling ice crystal shape in ice cream. International Patent Publication WO 99/37782 describes the isolation of AFPs from grasses and the use of such AFPs in frozen food products, such as ice cream and frozen yogurt. A particularly attractive trait, which is exhibited by *Lolium* AFPs, is their stability at high temperature (Pudney *et al.*, *Archiv. Biochem. Biophys.* 410:238-245, 2003). This lends itself to applications 20 within the food industry where high temperature treatments, such as pasteurization, are routinely used to inhibit microbial proliferation. AFPs may also be used in meat products to preserve texture and flavor after cold storage.

The ability to alter ice recrystallization may have wider applications within industrial crystallization processes. One example is separation, purification and 25 consistency in the production of pharmaceuticals, agrochemicals and pigments. AFPs could also be employed in the sugar industry where controlling crystal formation is highly desirable.

Another area where the manipulation of crystal architecture is desirable is in healthcare. AFPs could be localized in tumours where their propensity to form 30 hexagonal bipyramids would facilitate cellular damage. This type of treatment is particularly attractive because it is minimally invasive and does not have the accompanying negative side effects associated with traditional chemotherapy. Other healthcare applications include controlling the formation of biocrystals in disorders such as gout and in kidney stones.

It has been postulated that AFPs affect crystal formation by interfering with the molecular interactions between water molecules, see Jia and Davies, *Trends in Biochemical Science* 27:101-106, 2002. This could be used to assist the drying of, for example, dairy products or pharmaceuticals where a major component of process costs 5 is incurred as part of the drying process.

Summary of the Invention

The present invention provides antifreeze proteins that are encoded by polynucleotides isolated from forage grass tissues. The polynucleotides were isolated 10 from *Lolium perenne* (perennial ryegrass) and *Festuca arundinacea* (tall fescue) tissues taken at different times of the year, specifically in winter and spring, and from different parts of the plants, including: leaf blades, leaf base, pseudostems, roots and stems. The present invention also provides genetic constructs, expression vectors and host cells comprising the inventive polynucleotides, and methods for using the inventive 15 polynucleotides and genetic constructs to modulate the cold tolerance of organisms, such as plants.

In specific embodiments, the isolated polynucleotides of the present invention comprise a sequence selected from the group consisting of: (a) SEQ ID NO: 1-12 and 25; (b) complements of SEQ ID NO: 1-12 and 25; (c) reverse complements of SEQ ID 20 NO: 1-12 and 25; (d) reverse sequences of SEQ ID NO: 1-12 and 25; (e) sequences having a 99% probability of being functionally or evolutionarily related to a sequence of (a)-(d), determined as described below; and (f) sequences having at least 75%, 80%, 90%, 95% or 98% identity to a sequence of (a)-(d), the percentage identity being determined as described below. Polynucleotides comprising at least a specified number 25 of contiguous residues ("x-mers") of any of SEQ ID NO: 1-12 and 25; and oligonucleotide probes and primers corresponding to SEQ ID NO: 1-12 and 25 are also provided. All of the above polynucleotides are referred to herein as "polynucleotides of the present invention."

In further aspects, the present invention provides isolated polypeptides encoded 30 by the inventive polynucleotides. In specific embodiments, such polypeptides comprise an amino acid sequence of SEQ ID NO: 13-24 and 26. Polypeptides comprising a sequence having at least 75%, 80%, 90%, 95% or 98% identity to a sequence of SEQ ID NO: 13-24 and 26, wherein the polypeptide possesses the same functional activity as the polypeptide comprising a sequence of SEQ ID NO: 13-24 and 26 are also provided.

The present invention further contemplates isolated polypeptides comprising at least a functional portion of a polypeptide comprising an amino acid sequence selected from the group consisting of: (a) SEQ ID NO: 13-24 and 26; and (b) sequences having at least 75%, 80%, 90%, 95% or 98% identity to a sequence of SEQ ID NO: 13-24 and 26.

5 In another aspect, the present invention provides genetic constructs comprising a polynucleotide of the present invention, either alone or in combination with one or more of the inventive sequences, or in combination with one or more known polynucleotides.

In addition, the present invention provides methods for the production of polypeptides derived from the inventive polynucleotides such that monomeric or 10 multimeric forms of the same or different polypeptides are generated. This type of construct has been identified as offering enhanced activity, see Baardnes *et al.*, *J. Biol. Chem.* in press, 2003, Miura *et al.*, *J. Biol. Chem.* 276: 1304-1310, 2001, and Nishimiya *et al.*, *J. Biol. Chem.* 278:32307-32312, 2003.

In certain embodiments, the present invention provides genetic constructs 15 comprising, in the 5'-3' direction: a gene promoter sequence; an open reading frame coding for at least a functional portion of a polypeptide of the present invention; and a gene termination sequence. An open reading frame may be orientated in either a sense or anti-sense direction. Genetic constructs comprising a non-coding region of a polynucleotide of the present invention or a polynucleotide complementary to a non- 20 coding region, together with a gene promoter sequence and a gene termination sequence, are also provided. Preferably, the gene promoter and termination sequences are functional in a host cell, such as a plant cell. Most preferably, the gene promoter and termination sequences are those of the original enzyme genes but others generally used in the art, such as the Cauliflower Mosaic Virus (CMV) promoter, with or without 25 enhancers, such as the Kozak sequence or Omega enhancer, and *Agrobacterium tumefaciens* nopaline synthase terminator may be usefully employed in the present invention. Tissue-specific promoters may be employed in order to target expression to one or more desired tissues. The construct may further include a marker for the identification of transformed cells.

30 In a further aspect, transgenic cells, such as transgenic plant cells, comprising the constructs of the present invention are provided, together with tissues and plants comprising such transgenic cells, and fruits, seeds and other products, derivatives, or progeny of such plants.

In yet another aspect, methods for modulating the cold tolerance of a target organism, such as a plant, are provided, such methods including stably incorporating into the genome of the target organism a genetic construct comprising a polynucleotide of the present invention. In a preferred embodiment, the target organism is a plant, 5 preferably selected from the group consisting of commercially important trees and crop plants.

In a related aspect, a method for producing an organism or cell line, for example a prokaryotic or eukaryotic organism or cell line, such as a bacterium, yeast, mammalian cell line or plant, having increased cold tolerance is provided, the method 10 comprising transforming a cell with a genetic construct comprising of the present invention to provide a transgenic cell, and cultivating the transgenic cell under conditions conducive to regeneration and mature growth.

In yet a further aspect, the present invention provides methods for modifying the activity of an antifreeze protein in a target organism, such as a plant, comprising stably 15 incorporating into the genome of the target organism a genetic construct of the present invention.

The present invention further provides methods of cryopreserving cells, tissues or organisms, such methods comprising contacting the cell, tissue or organism to be preserved with a polypeptide of the present invention. Such cells, tissues and 20 organisms may be selected, for example, from the group consisting of: mammals, plants, insects, fungi and bacteria.

In related applications molecular biology reagents, such as buffers, enzymes and *in vitro* protein synthesis systems, containing a polypeptide of the present invention are provided. Food additives comprising a polypeptide of the present invention are also 25 provided, together with frozen food products comprising such food additives. In certain embodiments, such frozen food products are selected from the group consisting of: frozen fruit, frozen vegetables, ice cream, frozen yogurt, sherbet, sorbet, ice milk, water-ices, granites, frozen fruit purees and frozen meats. Preferably the amount of the inventive AFP within such products is from 0.00001 to 0.5%, by weight.

30 In another aspect, the inventive polypeptides may be employed as additives in industrial crystallization processes used in the separation and/or purification of compounds, or as components to improve consistency, for example, in pharmaceutical or agrochemical pigment production, or in the production of sugar and other crystalline materials. The polypeptides of the present invention may thus be usefully employed in

conjunction with known processes for the crystallization of sugar, such as those described in US Patents 4,216,025 and 5,286,298, and known processes for the production of pharmaceuticals, agrochemicals and pigments, such as that described in US Patent 6,506,886. The ability of a polypeptide of the present invention to directly 5 impact crystal formation in sucrose solutions has been demonstrated in a SPLAT ice-recrystallization assay, as described below in Example 3.

The inventive polypeptides may also be employed in therapeutic agents for the inhibition, disruption and/or restructuring of the crystal architecture within biocrystals associated with disorders such as gout and kidney stones. The inventive polypeptides 10 may also be introduced into unwanted tissue, such as tumors to promote cellular damage upon freezing when accompanied by a localized application of low temperature on or around the tumor site, as detailed, for example, in US Patent 5,654,279.

In addition, the inventive polypeptides may be employed in industrial or manufacturing processes to accelerate drying, such as in the production of foodstuffs 15 such as milk, and in the pharmaceutical industry where various drying technologies are used, for example freeze-drying and spray drying.

Brief Description of the Drawings

Fig. 1 shows the amino acid sequence of SEQ ID NO: 13, a *Lolium perenne* 20 antifreeze protein. The signal sequence is underlined, and the 7-amino acid sequence repeat region identified in antifreeze proteins (Sidebottom *et al.*, *Nature* 406:256, 2000; Kuiper *et al.*, *Biophys. J.* 81:3560-3565, 2001) is boxed. A conserved lipoprotein membrane attachment site is in bold and italics, and conserved Cys-pairs identified N-terminal of leucine-rich repeats of receptor-like kinases (Van der Knaap *et al.*, *Plant 25 Physiol.* 120:559-569, 1999) are double underlined.

Fig. 2 shows the amino acid sequence of SEQ ID NO: 14, a *Festuca arundinacea* antifreeze protein homolog. The signal sequence is underlined, the 7-amino acid sequence repeat region identified in antifreeze proteins (Sidebottom *et al.*, *Nature* 406:256, 2000; Kuiper *et al.*, *Biophys. J.* 81:3560-3565, 2001) is boxed and 30 conserved Cys-pairs identified N-terminal of leucine-rich repeats of receptor-like kinases (Van der Knaap *et al.*, *Plant Physiol.* 120:559-569, 1999) are double underlined.

Fig. 3 shows the amino acid sequence of SEQ ID NO: 15, a *Lolium perenne* antifreeze protein homolog. The signal sequence is underlined, and the 7-amino acid

sequence repeat region identified in antifreeze proteins (Sidebottom *et al.*, *Nature* 406:256, 2000; Kuiper *et al.*, *Biophys. J.* 81:3560-3565, 2001) is boxed. Conserved leucine-rich repeats are in bold and underlined (Worrall *et al.*, *Science* 282:115-117, 1998) and cysteine-pairs with the conserved amino acid sequence of cysteine pairs found N-terminal of leucine-rich repeats of receptor-like kinases (Van der Knaap *et al.*, *Plant Physiol.* 120:559-569, 1999) are double underlined.

Fig. 4 shows the amino acid sequence of SEQ ID NO: 16, a *Festuca arundinacea* antifreeze protein homolog. The signal sequence is underlined, and the 7-amino acid sequence repeat region identified in antifreeze proteins (Sidebottom *et al.*, *Nature* 406:256, 2000; Kuiper *et al.*, *Biophys. J.* 81:3560-3565, 2001) is boxed. Conserved leucine-rich repeats are in bold and underlined (Worrall *et al.*, *Science* 282:115-117, 1998) and cysteine-pairs with the conserved amino acid sequence of cysteine pairs found N-terminal of leucine-rich repeats of receptor-like kinases (Van der Knaap *et al.*, *Plant Physiol.* 120:559-569, 1999) are double underlined.

Fig. 5 shows the amino acid sequence of SEQ ID NO: 17, a *Lolium perenne* antifreeze protein homolog. The signal sequence is underlined, the 7-amino acid sequence repeat region identified in antifreeze proteins (Sidebottom *et al.*, *Nature* 406:256, 2000; Kuiper *et al.*, *Biophys. J.* 81:3560-3565, 2001) is boxed and a conserved lipoprotein membrane attachment site is in bold and italics. Conserved leucine-rich repeats are in bold and underlined (Worrall *et al.*, *Science* 282:115-117, 1998) and cysteine-pairs with the conserved amino acid sequence of cysteine pairs found N-terminal of leucine-rich repeats of receptor-like kinases (Van der Knaap *et al.*, *Plant Physiol.* 120:559-569, 1999) are double underlined.

Fig. 6 shows the amino acid sequence of SEQ ID NO: 18, a *Festuca arundinacea* antifreeze protein homolog. The signal sequence is underlined, and the 7-amino acid sequence repeat region identified in antifreeze proteins (Sidebottom *et al.*, *Nature* 406:256, 2000; Kuiper *et al.*, *Biophys. J.* 81:3560-3565, 2001) is boxed and a conserved lipoprotein membrane attachment site is in bold and italics. Conserved leucine-rich repeats are in bold and underlined (Worrall *et al.*, *Science* 282:115-117, 1998) and cysteine-pairs with the conserved amino acid sequence of cysteine pairs found N-terminal of leucine-rich repeats of receptor-like kinases (Van der Knaap *et al.*, *Plant Physiol.* 120:559-569, 1999) are double underlined.

Fig. 7 shows the amino acid sequence of SEQ ID NO: 19, a *Lolium perenne* antifreeze protein homolog. The signal sequence is underlined, and the 7-amino acid

sequence repeat region identified in antifreeze proteins (Sidebottom *et al.*, *Nature* 406:256, 2000; Kuiper *et al.*, *Biophys. J.* 81:3560-3565, 2001) is boxed. Conserved leucine-rich repeats are in bold and underlined (Worrall *et al.*, *Science* 282:115-117, 1998) and cysteine-pairs with the conserved amino acid sequence of cysteine pairs found N-terminal of leucine-rich repeats of receptor-like kinases (Van der Knaap *et al.*, *Plant Physiol.* 120:559-569, 1999) are double underlined.

Fig. 8 shows the amino acid sequence of SEQ ID NO: 20, a *Lolium perenne* antifreeze protein homolog. The signal sequence and transmembrane domain are underlined, and the 7-amino acid sequence repeat region identified in antifreeze proteins (Sidebottom *et al.*, *Nature* 406:256, 2000; Kuiper *et al.*, *Biophys. J.* 81:3560-3565, 2001) is boxed. A conserved lipoprotein membrane attachment site is in bold and italics. Conserved leucine-rich repeats are in bold and underlined (Worrall *et al.*, *Science* 282:115-117, 1998) and cysteine-pairs with the conserved amino acid sequence of cysteine pairs found N-terminal of leucine-rich repeats of receptor-like kinases (Van der Knaap *et al.*, *Plant Physiol.* 120:559-569, 1999) are double underlined.

Fig. 9 shows the amino acid sequence of SEQ ID NO: 21, a *Festuca arundinacea* antifreeze protein homolog. The signal sequence and transmembrane domain are underlined, and the 7-amino acid sequence repeat region identified in antifreeze proteins (Sidebottom *et al.*, *Nature* 406:256, 2000; Kuiper *et al.*, *Biophys. J.* 81:3560-3565, 2001) is boxed. Conserved leucine-rich repeats are in bold and underlined (Worrall *et al.*, *Science* 282:115-117, 1998) and cysteine-pairs with the conserved amino acid sequence of cysteine pairs found N-terminal of leucine-rich repeats of receptor-like kinases (Van der Knaap *et al.*, *Plant Physiol.* 120:559-569, 1999) are double underlined. A conserved lipoprotein membrane attachment site is in bold and italics.

Fig. 10 shows the amino acid sequence of SEQ ID NO: 22, a *Lolium perenne* antifreeze protein homolog. The signal sequence is underlined, and the 7-amino acid sequence repeat region identified in antifreeze proteins (Sidebottom *et al.*, *Nature* 406:256, 2000; Kuiper *et al.*, *Biophys. J.* 81:3560-3565, 2001) is boxed. Conserved leucine-rich repeats are in bold and underlined (Worrall *et al.*, *Science* 282:115-117, 1998) and cysteine-pairs with the conserved amino acid sequence of cysteine pairs found N-terminal of leucine-rich repeats of receptor-like kinases (Van der Knaap *et al.*, *Plant Physiol.* 120:559-569, 1999) are double underlined.

Fig. 11 shows the amino acid sequence of SEQ ID NO: 23, a *Festuca arundinacea* antifreeze protein homolog. The signal sequence is underlined, and the 7-amino acid sequence repeat region identified in antifreeze proteins (Sidebottom *et al.*, *Nature* 406:256, 2000; Kuiper *et al.*, *Biophys. J.* 81:3560-3565, 2001) is boxed.

5 Conserved leucine-rich repeats are in bold and underlined (Worrall *et al.*, *Science* 282:115-117, 1998) and cysteine-pairs with the conserved amino acid sequence of cysteine pairs found N-terminal of leucine-rich repeats of receptor-like kinases (Van der Knaap *et al.*, *Plant Physiol.* 120:559-569, 1999) are double underlined.

Fig. 12 shows the amino acid sequence of SEQ ID NO: 24, a *Lolium perenne* antifreeze protein homolog. The signal sequence is underlined, and the 7-amino acid sequence repeat region identified in antifreeze proteins (Sidebottom *et al.*, *Nature* 406:256, 2000; Kuiper *et al.*, *Biophys. J.* 81:3560-3565, 2001) is boxed. Conserved leucine-rich repeats are in bold and underlined (Worrall *et al.*, *Science* 282:115-117, 1998) and cysteine-pairs with the conserved amino acid sequence of cysteine pairs found N-terminal of leucine-rich repeats of receptor-like kinases (Van der Knaap *et al.*, *Plant Physiol.* 120:559-569, 1999) are double underlined.

Fig. 13 shows the amino acid sequence of SEQ ID NO: 26, a *Lolium perenne* antifreeze protein homolog. The signal sequence is underlined, and the 7-amino acid sequence repeat region identified in antifreeze proteins (Sidebottom *et al.*, *Nature* 406:256, 2000; Kuiper *et al.*, *Biophys. J.* 81:3560-3565, 2001) is boxed. Conserved leucine-rich repeats are in bold and underlined (Worrall *et al.*, *Science* 282:115-117, 1998) and cysteine-pairs with the conserved amino acid sequence of cysteine pairs found N-terminal of leucine-rich repeats of receptor-like kinases (Van der Knaap *et al.*, *Plant Physiol.* 120:559-569, 1999) are double underlined.

Detailed Description of the Invention

The polypeptides of the present invention, and the polynucleotides encoding the polypeptides, have activity in cold tolerance and anti-freeze pathways in plants. Using the methods and materials of the present invention, the cold tolerance of a plant may be modulated by modulating expression of polynucleotides of the present invention, or by modifying the polynucleotides or the polypeptides encoded by such polynucleotides. The isolated polynucleotides and polypeptides of the present invention may thus be usefully employed in improving cold tolerance in any plant, thereby improving its performance and extending the range of climates in which it may be grown.

The cold tolerance of an organism, such as a plant, may be modified by incorporating additional copies of polynucleotides encoding the inventive anti-freeze proteins into the genome of the target organism. In addition, cold or freezing tolerance of mammalian, plant, insect, bacteria, archaea and fungal cells or tissues may be 5 modified by incorporating additional copies of the inventive polynucleotides into the genome of the cells or tissues. The polynucleotides introduced may be in monomeric or multimeric form, composed of repeat units of the same specified polynucleotide or in combination with any of the other inventive polynucleotide sequences. The polypeptides encoded by the inventive anti-freeze protein polynucleotides can also be 10 usefully employed in the cryopreservation of mammalian, plant, insect, bacteria, archaea and fungal cells or tissues.

Plant AFPs have demonstrated ice restructuring activity (Hon *et al.*, *Plant Physiol.* 109:879-889, 1995; Sidebottom *et al.*, *Nature* 406:256, 2000 and Pudney *et al.*, *Arch. Biochem. Biophys.* 410:238-245, 2003), which can be enhanced by generating 15 multimeric forms, see Baardnes *et al.*, *J. Biol. Chem.* in press, 2003, and Nishimiya *et al.*, *J. Biol. Chem.* 278:32307-32312, 2003. The polypeptides of the present invention, used either individually, in multiples thereof or as engineered polypeptides consisting of individual or multiple units of the same or different inventive polypeptides, may be employed to modify crystallization processes. Applications within healthcare relate to 20 cryosurgery, as described, for example, in US Patent 5,654,279 and the modification of biocrystals such as those associated with gout and kidney stones. In food, the inventive polypeptides have applications in maintaining flavor and texture, by offsetting the damage caused by the formation of large ice crystals. Their ability to change the structure of ice cream, for example, permits a lower level of fat incorporation while 25 maintaining a desirable consistency. This has the health benefits of reducing fat content and therefore generating a product with a lower calorific value per gram weight.

Alternatively the polypeptides of the present invention, used either individually, in multiples thereof or as engineered polypeptides consisting of individual or multiple units of the same or different inventive polypeptides, may be usefully employed in 30 manufacturing processes which use a crystallization process to purify, separate, or maintain consistency, by controlling the size and/or rate of crystal formation. This has useful application in the pharmaceutical, agrochemical and pigment industries, and may also be employed in the food industry where the propagation of regular crystals is desirable, for example in the production of sugar.

Jia and Davies (*Trends in Biochemical Science* 27:101-106, 2002) have indicated that AFP mechanisms involve hydrogen, Van der Waals and hydrophobic interactions. As demonstrated below, the inventive polypeptides, used either individually, in multiples thereof or as engineered polypeptides consisting of individual 5 or multiple units of the same or different inventive polypeptides, may be employed in drying processes to increase the rate of dehydration.

In one aspect, the present invention provides methods for modulating the cold tolerance of an organism, such methods involving stably incorporating into the genome of the organism a genetic construct comprising one or more polynucleotides of the 10 present invention. In related aspects, methods for producing an organism having an altered genotype or phenotype is provided, such methods comprising transforming a cell with a genetic construct of the present invention to provide a transgenic cell, and cultivating the transgenic cell under conditions conducive to regeneration and mature growth. Organisms, such as plants, having an altered genotype or phenotype as a 15 consequence of modulation of the level or content of a polynucleotide or polypeptide of the present invention compared to a wild-type organism, as well as components (seeds, etc.) of such organisms, and the progeny of such organisms, are contemplated by and encompassed within the present invention.

Target cells which may be usefully transformed with the genetic constructs of 20 the present invention include plant, mammalian, insect, fungal, archaea and bacterial cells. In one embodiment, the target organism is a plant species, preferably a cold sensitive plant, such as a cold sensitive tree or cold sensitive crop plant. Examples of cold sensitive trees include eucalyptus species. Examples of cold sensitive crop plants include rice, sugarcane and tropical fruit and vegetable plants. Other plants that may be 25 usefully transformed with the inventive genetic constructs include herbs, ornamental shrubs and flowering plants.

Additionally, the polynucleotide sequences identified as SEQ ID NOS: 1-12 and 25 and their variants, may be used to design oligonucleotide probes and primers. Oligonucleotide probes and primers have sequences that are substantially 30 complementary to the polynucleotide of interest over a certain portion of the polynucleotide. Oligonucleotide probes designed using the polynucleotides of the present invention may be employed to detect the presence and examine the expression patterns of genes in any organism having sufficiently similar DNA and RNA sequences in their cells using techniques that are well known in the art, such as slot blot DNA

hybridization techniques. Oligonucleotide primers designed using the polynucleotides of the present invention may be used for PCR amplifications. Oligonucleotide probes and primers designed using the polynucleotides of the present invention may also be used in connection with various microarray technologies, including the microarray 5 technology of Affymetrix Inc. (Santa Clara, CA).

In a first aspect, the present invention provides isolated polynucleotide sequences identified in the attached Sequence Listing as SEQ ID NO: 1-12 and 25, and polypeptide sequences identified in the attached Sequence Listing as SEQ ID NO: 13-24 and 26. The polynucleotides and polypeptides of the present invention have 10 demonstrated similarity to the following antifreeze proteins:

TABLE 1

SEQ ID NO: DNA	SEQ ID NO: polypeptide	Description
1	13	Homologue isolated from <i>Lolium perenne</i> of an antifreeze protein that is involved in inhibition of ice crystal growth in plants. In the amino acid sequence, a 7-amino acid repeat (X X N X V X G) was identified (Kuiper <i>et al.</i> , <i>Biophys. J.</i> 81:3560-3565, 2001). The amino acid sequence and conserved domains are shown in Fig. 1.
2	14	Homologue isolated from <i>Festuca arundinacea</i> of an antifreeze protein that is involved in inhibition of ice crystal growth in plants. In the amino acid sequence, a 7-amino acid repeat (X X N X V X G) was identified (Kuiper <i>et al.</i> , <i>Biophys. J.</i> 81:3560-3565, 2001). The amino acid sequence and conserved domains are shown in Fig. 2.
3	15	Homologue isolated from <i>Lolium perenne</i> of an antifreeze protein that is involved in inhibition of ice crystal growth in plants. In the amino acid sequence, a 7-amino acid repeat (X X N X V X G) was identified (Kuiper <i>et al.</i> , <i>Biophys. J.</i> 81:3560-3565, 2001). The amino acid sequence and conserved domains are shown in Fig. 3.
4	16	Homologue isolated from <i>Festuca arundinacea</i> of an antifreeze protein that is involved in inhibition of ice crystal growth in plants. In the amino acid sequence, a 7-amino acid repeat (X X N X V X G) was identified (Kuiper <i>et al.</i> , <i>Biophys. J.</i> 81:3560-3565, 2001). The amino acid sequence and conserved domains are shown in Fig. 4.

		growth in plants. In the amino acid sequence, a 7-amino acid repeat (X X N X V X G) was identified (Kuiper <i>et al.</i> , <i>Biophys. J.</i> 81:3560-3565, 2001). The amino acid sequence and conserved domains are shown in Fig. 5
6	18	Homologue isolated from <i>Festuca arundinacea</i> of an antifreeze protein that is involved in inhibition of ice crystal growth in plants. In the amino acid sequence, a 7-amino acid repeat (X X N X V X G) was identified (Kuiper <i>et al.</i> , <i>Biophys. J.</i> 81:3560-3565, 2001). The amino acid sequence and conserved domains are shown in Fig. 6
7	19	Homologue isolated from <i>Lolium perenne</i> of an antifreeze protein that is involved in inhibition of ice crystal growth in plants. In the amino acid sequence, a 7-amino acid repeat (X X N X V X G) was identified (Kuiper <i>et al.</i> , <i>Biophys. J.</i> 81:3560-3565, 2001). The amino acid sequence and conserved domains are shown in Fig. 7
8	20	Homologue isolated from <i>Lolium perenne</i> of an antifreeze protein that is involved in inhibition of ice crystal growth in plants. In the amino acid sequence, a 7-amino acid repeat (X X N X V X G) was identified (Kuiper <i>et al.</i> , <i>Biophys. J.</i> 81:3560-3565, 2001). The amino acid sequence and conserved domains are shown in Fig. 8
9	21	Homologue isolated from <i>Festuca arundinacea</i> of an antifreeze protein that is involved in inhibition of ice crystal growth in plants. In the amino acid sequence, a 7-amino acid repeat (X X N X V X G) was identified (Kuiper <i>et al.</i> , <i>Biophys. J.</i> 81:3560-3565, 2001). The amino acid sequence and conserved domains are shown in Fig. 9.
10	22	Homologue isolated from <i>Lolium perenne</i> of an antifreeze protein that is involved in inhibition of ice crystal growth in plants. In the amino acid sequence, a 7-amino acid repeat (X X N X V X G) was identified (Kuiper <i>et al.</i> , <i>Biophys. J.</i> 81:3560-3565, 2001). The amino acid sequence and conserved domains are shown in Fig. 10.
11	23	Homologue isolated from <i>Festuca arundinacea</i> of an antifreeze protein that is involved in inhibition of ice crystal growth in plants. In the amino acid sequence, a 7-amino acid repeat (X X N X V X G) was identified (Kuiper <i>et al.</i> , <i>Biophys. J.</i> 81:3560-3565, 2001). The amino acid sequence and conserved domains are shown in Fig. 11.
12	24	Homologue isolated from <i>Lolium perenne</i> of an antifreeze protein that is involved in inhibition of ice crystal growth in plants. In the amino acid sequence, a 7-amino acid repeat (X X N X V X G) was identified (Kuiper <i>et al.</i> , <i>Biophys. J.</i> 81:3560-3565, 2001). The amino acid

SEQ ID NO: DNA	SEQ ID NO: polypeptide	Description
		sequence and conserved domains are shown in Fig. 12.
25	26	Homologue isolated from <i>Lolium perenne</i> of an antifreeze protein that is involved in inhibition of ice crystal growth in plants. In the amino acid sequence, a 7-amino acid repeat (X X N X V X G) was identified (Kuiper <i>et al.</i> , <i>Biophys. J.</i> 81:3560-3565, 2001). The amino acid sequence and conserved domains are shown in Fig. 13.

As used herein, the term "antifreeze protein" refers to proteins that possess an ability to inhibit, or alter the growth of ice crystals. As discussed above, these proteins bind to ice crystals thereby inhibiting their growth, and enabling some plants and organisms to survive under freezing conditions (Kuiper *et al.*, *Biophys. J.* 81:3560-3565, 2001). The antifreeze proteins are generally hydrophilic and are high in asparagine, valine, serine, and threonine residues (Sidebottom *et al.*, *Nature* 406:256, 2000).

10 All the polynucleotides and polypeptides provided by the present invention are isolated and purified, as those terms are commonly used in the art. Preferably, the polypeptides and polynucleotides are at least about 80% pure, more preferably at least about 90% pure, and most preferably at least about 99% pure.

The word "polynucleotide(s)," as used herein, means a polymeric collection of 15 nucleotides, and includes DNA and corresponding RNA molecules and both single and double stranded molecules, including HnRNA and mRNA molecules, sense and anti-sense strands of DNA and RNA molecules, and comprehends cDNA, genomic DNA, and wholly or partially synthesized polynucleotides. A polynucleotide of the present invention may be an entire gene, or any portion thereof. As used herein, a "gene" is a 20 DNA sequence which codes for a functional protein or RNA molecule. Operable anti-sense polynucleotides may comprise a fragment of the corresponding polynucleotide, and the definition of "polynucleotide" therefore includes all operable anti-sense fragments. Anti-sense polynucleotides and techniques involving anti-sense polynucleotides are well known in the art and are described, for example, in Robinson- 25 Benion *et al.*, *Methods in Enzymol.* 254(23): 363-375, 1995 and Kawasaki *et al.*, *Artific. Organs* 20(8): 836-848, 1996.

In specific embodiments, the present invention provides isolated polynucleotides comprising a sequence of SEQ ID NO: 1-12 or 25; polynucleotides comprising variants of SEQ ID NO: 1-12 or 25; polynucleotides comprising extended sequences of SEQ ID NO: 1-12 or 25 and their variants, oligonucleotide primers and probes corresponding to the sequences set out in SEQ ID NO: 1-12 or 25 and their variants, polynucleotides comprising at least a specified number of contiguous residues of any of SEQ ID NO: 1-12 or 25 (x -mers), and polynucleotides comprising extended sequences which include portions of the sequences set out in SEQ ID NO: 1-12 and 25, all of which are referred to herein, collectively, as "polynucleotides of the present invention." Polynucleotides that comprise complements of such polynucleotide sequences, reverse complements of such polynucleotide sequences, or reverse sequences of such polynucleotide sequences, together with variants of such sequences, are also provided.

The definition of the terms "complement(s)," "reverse complement(s)," and "reverse sequence(s)," as used herein, is best illustrated by the following example. For the sequence 5' AGGACC 3', the complement, reverse complement, and reverse sequence are as follows:

	complement	3' TCCTGG 5'
	reverse complement	3' GGTCTT 5'
20	reverse sequence	5' CCAGGA 3'.

Preferably, sequences that are complements of a specifically recited polynucleotide sequence are complementary over the entire length of the specific polynucleotide sequence.

As used herein, the term " x -mer," with reference to a specific value of " x ," refers to a polynucleotide comprising at least a specified number (" x ") of contiguous residues of: any of the polynucleotides provided in SEQ ID NO: 1-12 and 25. The value of x may be from about 20 to about 600, depending upon the specific sequence.

Polynucleotides of the present invention comprehend polynucleotides comprising at least a specified number of contiguous residues (x -mers) of any of the 30 polynucleotides identified as SEQ ID NO: 1-12 and 25, or their variants. Similarly, polypeptides of the present invention comprehend polypeptides comprising at least a specified number of contiguous residues (x -mers) of any of the polypeptides identified as SEQ ID NO: 13-24 and 26. According to preferred embodiments, the value of x is at least 20, more preferably at least 40, more preferably yet at least 60, and most

preferably at least 80. Thus, polynucleotides of the present invention include polynucleotides comprising a 20-mer, a 40-mer, a 60-mer, an 80-mer, a 100-mer, a 120-mer, a 150-mer, a 180-mer, a 220-mer, a 250-mer; or a 300-mer, 400-mer, 500-mer or 600-mer of a polynucleotide provided in SEQ ID NO: 1-12 and 25, or a variant of one 5 of the polynucleotides corresponding to the polynucleotides provided in SEQ ID NO: 1-12 and 25. Polypeptides of the present invention include polypeptides comprising a 20-mer, a 40-mer, a 60-mer, an 80-mer, a 100-mer, a 120-mer, a 150-mer, a 180-mer, a 220-mer, a 250-mer; or a 300-mer, 400-mer, 500-mer or 600-mer of a polypeptide provided in SEQ ID NO: 13-24 and 26, or a variant thereof.

10 Polynucleotides of the present invention were isolated by high throughput sequencing of cDNA libraries comprising forage grass tissue collected from *Lolium perenne* and *Festuca arundinacea*. Some of the polynucleotides of the present invention may be "partial" sequences, in that they do not represent a full-length gene encoding a full-length polypeptide. Such partial sequences may be extended by 15 analyzing and sequencing various DNA libraries using primers and/or probes and well known hybridization and/or PCR techniques. Partial sequences may be extended until an open reading frame encoding a polypeptide, a full-length polynucleotide and/or gene capable of expressing a polypeptide, or another useful portion of the genome is identified. Such extended sequences, including full-length polynucleotides and genes, 20 are described as "corresponding to" a sequence identified as one of the sequences of SEQ ID NO: 1-12 and 25 or a variant thereof, or a portion of one of the sequences of SEQ ID NO: 1-12 and 25 or a variant thereof, when the extended polynucleotide comprises an identified sequence or its variant, or an identified contiguous portion (x -mer) of one of the sequences of SEQ ID NOS: 1-12 and 25 or a variant thereof. 25 Similarly, RNA sequences, reverse sequences, complementary sequences, anti-sense sequences and the like, corresponding to the polynucleotides of the present invention, may be routinely ascertained and obtained using the cDNA sequences identified as SEQ ID NOS: 1-12 and 25.

The polynucleotides identified as SEQ ID NOS: 1-12 and 25 contain open 30 reading frames ("ORFs") encoding polypeptides and functional portions of polypeptides. Additionally, open reading frames encoding polypeptides may be identified in extended or full length sequences corresponding to the sequences set out as SEQ ID NOS: 1-12 and 25. Open reading frames may be identified using techniques that are well known in the art. These techniques include, for example, analysis for the

location of known start and stop codons, most likely reading frame identification based on codon frequencies, etc. Suitable tools and software for ORF analysis are well known in the art and include, for example, GeneWise, available from The Sanger Center, Wellcome Trust Genome Campus, Hinxton, Cambridge, CB10 1SA, United Kingdom; 5 Diogenes, available from Computational Biology Centers, University of Minnesota, Academic Health Center, UMHG Box 43, Minneapolis MN 55455; and GRAIL, available from the Informatics Group, Oak Ridge National Laboratories, Oak Ridge, Tennessee TN. Once a partial open reading frame is identified, the polynucleotide may be extended in the area of the partial open reading frame using techniques that are well 10 known in the art until the polynucleotide for the full open reading frame is identified.

Once open reading frames are identified in the polynucleotides of the present invention, the open reading frames may be isolated and/or synthesized. Expressible genetic constructs comprising the open reading frames and suitable promoters, initiators, terminators, etc., which are well known in the art, may then be constructed. 15 Such genetic constructs may be introduced into a host cell to express the polypeptide encoded by the open reading frame. Suitable host cells may include various prokaryotic and eukaryotic cells, including plant cells, mammalian cells, archaeal cells, bacterial cells, algae and the like.

The polynucleotides of the present invention may be isolated by high throughput 20 sequencing of cDNA libraries prepared from forage grass tissue, as described below in Example 1. Alternatively, oligonucleotide probes and primers based on the sequences provided in SEQ ID NOS: 1-12 and 25 can be synthesized as detailed below, and used to identify positive clones in either cDNA or genomic DNA libraries from forage grass tissue cells by means of hybridization or polymerase chain reaction (PCR) techniques. 25 Hybridization and PCR techniques suitable for use with such oligonucleotide probes are well known in the art (see, for example, Mullis *et al.*, *Cold Spring Harbor Symp. Quant. Biol.*, 51:263, 1987; Erlich, ed., *PCR technology*, Stockton Press: NY, 1989; and Sambrook *et al.*, eds., *Molecular cloning: a laboratory manual*, 2nd ed., CSHL Press: Cold Spring Harbor, NY, 1989). In addition to DNA-DNA hybridization, DNA-RNA 30 or RNA-RNA hybridization assays are also possible. In the first case, the mRNA from expressed genes would then be detected instead of genomic DNA or cDNA derived from mRNA of the sample. In the second case, RNA probes could be used. Artificial analogs of DNA hybridizing specifically to target sequences could also be employed.

Positive clones can be analyzed by using restriction enzyme digestion, DNA sequencing or the like.

The polynucleotides of the present invention may also, or alternatively, be synthesized using techniques that are well known in the art. The polynucleotides may 5 be synthesized, for example, using automated oligonucleotide synthesizers (e.g., Beckman Oligo 1000M DNA Synthesizer; Beckman Coulter Ltd., Fullerton, CA) to obtain polynucleotide segments of up to 50 or more nucleic acids. A plurality of such polynucleotide segments may then be ligated using standard DNA manipulation techniques that are well known in the art of molecular biology. One conventional and 10 exemplary polynucleotide synthesis technique involves synthesis of a single stranded polynucleotide segment having, for example, 80 nucleic acids, and hybridizing that segment to a synthesized complementary 85 nucleic acid segment to produce a 5 nucleotide overhang. The next segment may then be synthesized in a similar fashion, with a 5 nucleotide overhang on the opposite strand. The "sticky" ends ensure proper 15 ligation when the two portions are hybridized. In this way, a complete polynucleotide of the present invention may be synthesized entirely *in vitro*.

Oligonucleotide probes and primers complementary to and/or corresponding to SEQ ID NOS: 1-12 and 25 and variants of those sequences, are also comprehended by the present invention. Such oligonucleotide probes and primers are substantially 20 complementary to the polynucleotide of interest over a certain portion of the polynucleotide. An oligonucleotide probe or primer is described as "corresponding to" a polynucleotide of the present invention, including one of the sequences set out as SEQ ID NOS: 1-12 and 25 or a variant thereof, if the oligonucleotide probe or primer, or its complement, is contained within one of the sequences set out as SEQ ID NOS: 1-12 and 25 or a variant of one of the specified sequences.

Two single stranded sequences are said to be substantially complementary when the nucleotides of one strand, optimally aligned and compared, with the appropriate nucleotide insertions and/or deletions, pair with at least 80%, preferably at least 90% to 95%, and more preferably at least 98% to 100%, of the nucleotides of the other strand. 30 Alternatively, substantial complementarity exists when a first DNA strand will selectively hybridize to a second DNA strand under stringent hybridization conditions.

In specific embodiments, the oligonucleotide probes and/or primers comprise at least about 6 contiguous residues, more preferably at least about 10 contiguous residues, and most preferably at least about 20 contiguous residues complementary to a

polynucleotide sequence of the present invention. Probes and primers of the present invention may be from about 8 to 100 base pairs in length, preferably from about 10 to 50 base pairs in length, and more preferably from about 15 to 40 base pairs in length. The probes can be easily selected using procedures well known in the art, taking into account DNA-DNA hybridization stringencies, annealing and melting temperatures, potential for formation of loops, and other factors that are well known in the art. Preferred techniques for designing PCR primers are disclosed in Dieffenbach and Dyksler, *PCR Primer: a laboratory manual*, CSHL Press: Cold Spring Harbor, NY, 1995. A software program suitable for designing probes, and especially for designing PCR primers, is available from Premier Biosoft International, 3786 Corina Way, Palo Alto, CA 94303-4504.

The isolated polynucleotides of the present invention also have utility in genome mapping, in physical mapping, and in positional cloning of genes.

The polynucleotides identified as SEQ ID NOS: 1-12 and 25 were isolated from cDNA clones and represent sequences that are expressed in the tissue from which the cDNA was prepared. RNA sequences, reverse sequences, complementary sequences, anti-sense sequences, and the like, corresponding to the polynucleotides of the present invention, may be routinely ascertained and obtained using the cDNA sequences identified as SEQ ID NOS: 1-12 and 25.

Identification of genomic DNA and heterologous species DNA can be accomplished by standard DNA/DNA hybridization techniques, under appropriately stringent conditions, using all or part of a polynucleotide sequence as a probe to screen an appropriate library. Alternatively, PCR techniques using oligonucleotide primers that are designed based on known genomic DNA, cDNA and protein sequences can be used to amplify and identify genomic and cDNA sequences.

In another aspect, the present invention provides isolated polypeptides encoded by the above polynucleotides. As used herein, the term "polypeptide" encompasses amino acid chains of any length, including full-length proteins, wherein the amino acid residues are linked by covalent peptide bonds. The term "polypeptide encoded by a polynucleotide" as used herein, includes polypeptides encoded by a polynucleotide that comprises a partial isolated polynucleotide sequence provided herein. In specific embodiments, the inventive polypeptides comprise an amino acid sequence selected from the group consisting of SEQ ID NO: 13-24 and 26, as well as variants of such sequences.

As noted above, polypeptides of the present invention may be produced recombinantly by inserting a polynucleotide sequence of the present invention encoding the polypeptide into an expression vector and expressing the polypeptide in an appropriate host. Any of a variety of expression vectors known to those of ordinary skill in the art may be employed. Expression may be achieved in any appropriate host cell that has been transformed or transfected with an expression vector containing a polynucleotide molecule that encodes a recombinant polypeptide. Suitable host cells include prokaryotes, yeast, and higher eukaryotic cells. Preferably, the host cells employed are plant, *Escherichia coli*, insect, yeast, or a mammalian cell line such as 5 COS or CHO. The polynucleotide sequences expressed in this manner may encode naturally occurring polypeptides, portions of naturally occurring polypeptides, or other variants thereof. The expressed polypeptides may be used in various assays known in the art to determine their biological activity. Such polypeptides may also be used to raise antibodies, to isolate corresponding interacting proteins or other compounds, and 10 to quantitatively determine levels of interacting proteins or other compounds.

15

In a related aspect, polypeptides are provided that comprise at least a functional portion of a polypeptide having an amino acid sequence selected from the group consisting of sequences provided in SEQ ID NO: 13-24 and 26, and variants thereof. As used herein, the "functional portion" of a polypeptide is that portion which contains 20 an active site essential for affecting the function of the polypeptide, for example, that portion of the molecule that is capable of binding ice crystals. The active site may be made up of separate portions present on one or more polypeptide chains and will generally exhibit high binding affinity. Functional portions of a polypeptide may be identified by first preparing fragments of the polypeptide by either chemical or 25 enzymatic digestion of the polypeptide, or by mutation analysis of the polynucleotide that encodes the polypeptide and subsequent expression of the resulting mutant polypeptides. The polypeptide fragments or mutant polypeptides are then tested to determine which portions retain biological activity, using methods well known to those of skill in the art, including the representative assays described below.

30 Portions and other variants of the inventive polypeptides may be generated by synthetic or recombinant means. Synthetic polypeptides having fewer than about 100 amino acids, and generally fewer than about 50 amino acids, may be generated using techniques well known to those of ordinary skill in the art. For example, such polypeptides may be synthesized using any of the commercially available solid-phase

techniques, such as the Merrifield solid-phase synthesis method, where amino acids are sequentially added to a growing amino acid chain. *See* Merrifield, *J. Am. Chem. Soc.* 85: 2149-2146, 1963. Equipment for automated synthesis of polypeptides is commercially available from suppliers such as Perkin Elmer/Applied Biosystems, Inc. 5 (Foster City, California), and may be operated according to the manufacturer's instructions. Variants of a native polypeptide may be prepared using standard mutagenesis techniques, such as oligonucleotide-directed site-specific mutagenesis (Kunkel, *Proc. Natl. Acad. Sci. USA* 82: 488-492, 1985). Sections of DNA sequences may also be removed using standard techniques to permit preparation of truncated 10 polypeptides.

As used herein, the term "variant" comprehends nucleotide or amino acid sequences different from the specifically identified sequences, wherein one or more nucleotides or amino acid residues is deleted, substituted, or added. Variants may be naturally occurring allelic variants, or non-naturally occurring variants. Variant 15 sequences (polynucleotide or polypeptide) preferably exhibit at least 75%, more preferably at least 80%, more preferably at least 90%, more preferably yet at least 95%, and most preferably, at least 98% identity to a sequence of the present invention. The percentage identity is determined by aligning the two sequences to be compared as described below, determining the number of identical residues in the aligned portion, 20 dividing that number by the total number of residues in the inventive (queried) sequence, and multiplying the result by 100.

Polynucleotides and polypeptides having a specified percentage identity to a polynucleotide or polypeptide identified in one of SEQ ID NO: 1-26 thus share a high degree of similarity in their primary structure. In addition to a specified percentage 25 identity to a polynucleotide of the present invention, variant polynucleotides and polypeptides preferably have additional structural and/or functional features in common with a polynucleotide of the present invention. Polynucleotides having a specified degree of identity to, or capable of hybridizing to, a polynucleotide of the present invention preferably additionally have at least one of the following features: (1) they 30 contain an open reading frame, or partial open reading frame, encoding a polypeptide, or a functional portion of a polypeptide, having substantially the same functional properties as the polypeptide, or functional portion thereof, encoded by a polynucleotide in a recited SEQ ID NO.; or (2) they contain identifiable domains in common.

Polynucleotide or polypeptide sequences may be aligned, and percentages of identical nucleotides or amino acids in a specified region may be determined against another polynucleotide or polypeptide, using computer algorithms that are publicly available. The BLASTN and FASTA algorithms, set to the default parameters 5 described in the documentation and distributed with the algorithm, may be used for aligning and identifying the similarity of polynucleotide sequences. The alignment and similarity of polypeptide sequences may be examined using the BLASTP algorithm. BLASTX and FASTX algorithms compare nucleotide query sequences translated in all reading frames against polypeptide sequences. The FASTA and FASTX algorithms are 10 described in Pearson and Lipman, *Proc. Natl. Acad. Sci. USA* 85:2444-2448, 1988; and in Pearson, *Methods in Enzymol.* 183:63-98, 1990. The FASTA software package is available from the University of Virginia by contacting the Assistant Provost for Research, University of Virginia, PO Box 9025, Charlottesville, VA 22906-9025. The BLASTN software is available from the National Center for Biotechnology Information 15 (NCBI), National Library of Medicine, Building 38A, Room 8N805, Bethesda, MD 20894. The BLASTN algorithm Version 2.0.11 [Jan-20-2000] set to the default parameters described in the documentation and distributed with the algorithm, is preferred for use in the determination of polynucleotide variants according to the present invention. The use of the BLAST family of algorithms, including BLASTN, 20 BLASTP and BLASTX, is described in the publication of Altschul *et al.*, "Gapped BLAST and PSI-BLAST: a new generation of protein database search programs," *Nucleic Acids Res.* 25:3389-3402, 1997.

The following running parameters are preferred for determination of alignments and similarities using BLASTN that contribute to the E values and percentage identity 25 for polynucleotides: Unix running command with the following default parameters: blastall -p blastn -d embldb -e 10 -G 0 -E 0 -FF -r 1 -v 30 -b 30 -i queryseq -o results; and parameters are: -p Program Name [String]; -d Database [String]; -e Expectation value (E) [Real]; -G Cost to open a gap (zero invokes default behavior) [Integer]; -E Cost to extend a gap (zero invokes default behavior) [Integer]; -FF low complexity 30 filter; -r Reward for a nucleotide match (BLASTN only) [Integer]; -v Number of one-line descriptions (V) [Integer]; -b Number of alignments to show (B) [Integer]; -i Query File [File In]; -o BLAST report Output File [File Out] Optional.

The following running parameters are preferred for determination of alignments and similarities using BLASTP that contribute to the E values and percentage identity

of polypeptide sequences: blastall -p blastp -d swissprottrembledb -e 10 -G 0 -E 0 -FF -v 30 -b 30 -i queryseq -o results; the parameters are: -p Program Name [String]; -d Database [String]; -e Expectation value (E) [Real]; -G Cost to open a gap (zero invokes default behavior) [Integer]; -E Cost to extend a gap (zero invokes default behavior) [Integer]; -FF low complexity filter; -v Number of one-line descriptions (v) [Integer]; -b Number of alignments to show (b) [Integer]; -I Query File [File In]; -o BLAST report Output File [File Out] Optional.

The "hits" to one or more database sequences by a queried sequence produced by BLASTN, BLASTP, FASTA, or a similar algorithm, align and identify similar portions of sequences. The hits are arranged in order of the degree of similarity and the length of sequence overlap. Hits to a database sequence generally represent an overlap over only a fraction of the sequence length of the queried sequence.

As noted above, the percentage identity of a polynucleotide or polypeptide sequence is determined by aligning polynucleotide and polypeptide sequences using appropriate algorithms, such as BLASTN or BLASTP, respectively, set to default parameters; identifying the number of identical nucleic or amino acids over the aligned portions; dividing the number of identical nucleic or amino acids by the total number of nucleic or amino acids of the polynucleotide or polypeptide of the present invention; and then multiplying by 100 to determine the percentage identity. By way of example, a queried polynucleotide having 220 nucleic acids has a hit to a polynucleotide sequence in the EMBL database having 520 nucleic acids over a stretch of 23 nucleotides in the alignment produced by the BLASTN algorithm using the default parameters. The 23-nucleotide hit includes 21 identical nucleotides, one gap and one different nucleotide. The percentage identity of the queried polynucleotide to the hit in the EMBL database is thus 21/220 times 100, or 9.5%. The percentage identity of polypeptide sequences may be determined in a similar fashion.

The BLASTN and BLASTX algorithms also produce "Expect" values for polynucleotide and polypeptide alignments. The Expect value (E) indicates the number of hits one can "expect" to see over a certain number of contiguous sequences by chance when searching a database of a certain size. The Expect value is used as a significance threshold for determining whether the hit to a database indicates true similarity. For example, an E value of 0.1 assigned to a polynucleotide hit is interpreted as meaning that in a database of the size of the EMBL database, one might expect to see 0.1 matches over the aligned portion of the sequence with a similar score simply by

chance. By this criterion, the aligned and matched portions of the sequences then have a probability of 90% of being related. For sequences having an E value of 0.01 or less over aligned and matched portions, the probability of finding a match by chance in the EMBL database is 1% or less using the BLASTN algorithm. E values for polypeptide 5 sequences may be determined in a similar fashion using various polypeptide databases, such as the SwissProt database.

According to one embodiment, "variant" polynucleotides and polypeptides, with reference to each of the polynucleotides and polypeptides of the present invention, preferably comprise sequences having the same number or fewer nucleotides or amino 10 acids than each of the polynucleotides or polypeptides of the present invention and producing an E value of 0.01 or less when compared to the polynucleotide or polypeptide of the present invention. That is, a variant polynucleotide or polypeptide is any sequence that has at least a 99% probability of being related to the polynucleotide or polypeptide of the present invention, measured as having an E value of 0.01 or less 15 using the BLASTN or BLASTX algorithms set at the default parameters. According to a preferred embodiment, a variant polynucleotide is a sequence having the same number or fewer nucleic acids than a polynucleotide of the present invention that has at least a 99% probability of being related to the polynucleotide of the present invention, measured as having an E value of 0.01 or less using the BLASTN algorithm set at the 20 default parameters. Similarly, according to a preferred embodiment, a variant polypeptide is a sequence having the same number or fewer amino acids than a polypeptide of the present invention that has at least a 99% probability of being related as the polypeptide of the present invention, measured as having an E value of 0.01 or less using the BLASTP algorithm set at the default parameters.

25 In an alternative embodiment, variant polynucleotides are sequences that hybridize to a polynucleotide of the present invention under stringent conditions. Stringent hybridization conditions for determining complementarity include salt conditions of less than about 1 M, more usually less than about 500 mM, and preferably less than about 200 mM. Hybridization temperatures can be as low as 5°C, but are 30 generally greater than about 22°C, more preferably greater than about 30°C, and most preferably greater than about 37°C. Longer DNA fragments may require higher hybridization temperatures for specific hybridization. Since the stringency of hybridization may be affected by other factors such as probe composition, presence of organic solvents, and extent of base mismatching, the combination of parameters is

more important than the absolute measure of any one alone. An example of "stringent conditions" is prewashing in a solution of 6X SSC, 0.2% SDS; hybridizing at 65°C, 6X SSC, 0.2% SDS overnight; followed by two washes of 30 minutes each in 1X SSC, 0.1% SDS at 65°C and two washes of 30 minutes each in 0.2X SSC, 0.1% SDS at 65°C.

5 The present invention also encompasses polynucleotides that differ from the disclosed sequences but that, as a consequence of the discrepancy of the genetic code, encode a polypeptide having similar functional activity to a polypeptide encoded by a polynucleotide of the present invention. Thus, polynucleotides comprising sequences that differ from the polynucleotide sequences recited in SEQ ID NO: 1-12 and 25, or 10 complements, reverse sequences, or reverse complements of those sequences, as a result of conservative substitutions are contemplated by and encompassed within the present invention. Additionally, polynucleotides comprising sequences that differ from the polynucleotide sequences recited in SEQ ID NO: 1-12 and 25, or complements, reverse complements or reverse sequences thereof, as a result of deletions and/or insertions 15 totaling less than 10% of the total sequence length are also contemplated by and encompassed within the present invention. Similarly, polypeptides comprising sequences that differ from the polypeptide sequences recited in SEQ ID NO: 13-24 and 26 as a result of amino acid substitutions, insertions, and/or deletions totaling less than 10% of the total sequence length are contemplated by and encompassed within the 20 present invention, provided the variant polypeptide has activity in a lignin, fructan or tannin biosynthetic pathway.

In another aspect, the present invention provides genetic constructs comprising, in the 5'-3' direction, a gene promoter sequence; an open reading frame coding for at least a functional portion of a polypeptide of the present invention; and a gene 25 termination sequence. The open reading frame may be orientated in either a sense or anti-sense direction. For applications where amplification of cold tolerance is desired, the open reading frame may be inserted in the construct in a sense orientation, such that transformation of a target organism with the construct will lead to an increase in the number of copies of the gene and therefore an increase in the amount of polypeptide. 30 When down-regulation of cold tolerance is desired, the open reading frame may be inserted in the construct in an anti-sense orientation, such that the RNA produced by transcription of the polynucleotide is complementary to the endogenous mRNA sequence. This, in turn, will result in a decrease in the number of copies of the gene and

therefore a decrease in the amount of polypeptide. Alternatively, regulation may be achieved by inserting appropriate sequences or subsequences (e.g., DNA or RNA) in ribozyme constructs.

Genetic constructs comprising a non-coding region of a gene coding for a 5 polypeptide of the present invention, or a nucleotide sequence complementary to a non-coding region, together with a gene promoter sequence and a gene termination sequence, are also provided. As used herein the term "non-coding region" includes both transcribed sequences that are not translated, and non-transcribed sequences within about 2000 base pairs 5' or 3' of the translated sequences or open reading frames. 10 Examples of non-coding regions that may be usefully employed in the inventive constructs include introns and 5'-non-coding leader sequences. Transformation of a target organism with such a genetic construct may lead to a reduction in the cold tolerance the plant by the process of cosuppression, in a manner similar to that discussed, for example, by Napoli *et al.*, *Plant Cell* 2:279-290, 1990; and de Carvalho 15 Niebel *et al.*, *Plant Cell* 7:347-358, 1995.

The genetic constructs of the present invention further comprise a gene promoter sequence and a gene termination sequence, operably linked to the polynucleotide to be transcribed, which control expression of the gene. The gene promoter sequence is generally positioned at the 5' end of the polynucleotide to be transcribed, and is 20 employed to initiate transcription of the polynucleotide. Gene promoter sequences are generally found in the 5' non-coding region of a gene but they may exist in introns (Luehrs, *Mol. Gen. Genet.* 225:81-93, 1991). When the construct includes an open reading frame in a sense orientation, the gene promoter sequence also initiates translation of the open reading frame. For genetic constructs comprising either an open 25 reading frame in an anti-sense orientation or a non-coding region, the gene promoter sequence consists only of a transcription initiation site having a RNA polymerase binding site.

A variety of gene promoter sequences that may be usefully employed in the genetic constructs of the present invention are well known in the art. The promoter 30 gene sequence, and also the gene termination sequence, may be endogenous to the target host or may be exogenous, provided the promoter is functional in the target host. For example, the promoter and termination sequences may be from other plant species, plant viruses, bacterial or archaeal plasmids and the like. Preferably, gene promoter and termination sequences are from the inventive sequences themselves.

Factors influencing the choice of promoter include the desired tissue specificity of the construct, and the timing of transcription and translation. For example, constitutive promoters, such as the 35S Cauliflower Mosaic Virus (CaMV 35S) promoter, will affect the activity of the enzyme in all parts of the plant. Use of a tissue specific promoter will result in production of the desired sense or anti-sense RNA only in the tissue of interest. With genetic constructs employing inducible gene promoter sequences, the rate of RNA polymerase binding and initiation can be modulated by external physical or chemical stimuli, such as light, heat, anaerobic stress, alteration in nutrient conditions and the like. Temporally regulated promoters can be employed to effect modulation of the rate of RNA polymerase binding and initiation at a specific time during development of a transformed cell. Preferably, the original promoters from the gene in question, or promoters from a specific tissue-targeted gene in the organism to be transformed, such as *Lolium* or *Festuca*, are used. Promoters different from the original gene may also be usefully employed in the inventive genetic constructs in order to prevent feedback inhibition. Other examples of gene promoters which may be usefully employed in the present invention include, mannopine synthase (mas), octopine synthase (ocs) and those reviewed by Chua *et al.*, *Science* 244:174-181, 1989.

The gene termination sequence, which is located 3' to the polynucleotide to be transcribed, may come from the same gene as the gene promoter sequence or may be from a different gene. Many gene termination sequences known in the art may be usefully employed in the present invention, such as the 3' end of the *Agrobacterium tumefaciens* nopaline synthase gene. However, preferred gene terminator sequences are those from the original gene or from the target species to be transformed.

The genetic constructs of the present invention may also contain a selection marker that is effective in cells, such as plant cells, to allow for the detection of transformed cells containing the inventive construct. Such markers, which are well known in the art, typically confer resistance to one or more toxins. One example of such a marker is the NPTII gene whose expression results in resistance to kanamycin or hygromycin, antibiotics which are usually toxic to plant cells at a moderate concentration (Rogers *et al.*, in Weissbach A and H, eds., *Methods for Plant Molecular Biology*, Academic Press Inc.: San Diego, CA, 1988). Alternatively, the presence of the desired construct in transformed cells can be determined by means of other techniques well known in the art, such as Southern and Western blots.

Techniques for operatively linking the components of the inventive genetic constructs are well known in the art and include the use of synthetic linkers containing one or more restriction endonuclease sites as described, for example, by Sambrook *et al.*, (*Molecular cloning: a laboratory manual*, CSHL Press: Cold Spring Harbor, NY, 5 1989). The genetic construct of the present invention may be linked to a vector having at least one replication system, for example, *Escherichia coli*, whereby after each manipulation, the resulting construct can be cloned and sequenced and the correctness of the manipulation determined.

The genetic constructs of the present invention may be used to transform a 10 variety of organisms including mammals, insects, fungi, archaea and bacteria, in addition to plants, both monocotyledonous (e.g., grasses, maize/corn, grains, oats, rice, sorghum, millet, rye, sugar cane, wheat and barley), dicotyledonous (e.g., *Arabidopsis*, tobacco, legumes, alfalfa, oaks, eucalyptus, maple), and gymnosperms. In a preferred embodiment, the inventive genetic constructs are employed to transform grasses. 15 Preferably the target plant is selected from the group consisting of *Lolium* and *Festuca* species, most preferably from the group consisting of *Lolium perenne* and *Festuca arundinacea*. Other species of ryegrass and fescue that may be usefully transformed with the inventive genetic constructs, include, but are not limited to *Lolium multiflorum* (Italian ryegrass), *Lolium hybridum* (hybrid ryegrass), *Lolium rigidum* (Wimerra grass), 20 *Lolium temulentum* (darnel), *Festuca rubra* (red fescue) and *Festuca pratensis* (meadow fescue). Other plants that may be usefully transformed with the inventive genetic constructs include cold intolerant trees, such as eucalyptus, and high value crops, such as cherries, stone fruit (for example, peaches), apples, pears, walnuts, almonds, peanuts, wine grapes, potatoes and tomatoes. As discussed above, 25 transformation of a organism with a genetic construct of the present invention will produce a modified cold tolerance in the plant.

The production of RNA in target cells may be controlled by choice of the promoter sequence, or by selecting the number of functional copies or the site of integration of the polynucleotides incorporated into the genome of the target organism. 30 A target organism may be transformed with more than one construct of the present invention, thereby affecting AFP activity in more than one tissue or affecting AFP activity at more than one expression time. Similarly, a construct may be assembled containing more than one open reading frame coding for an AFP encoded by a polynucleotide of the present invention or more than one non-coding region of a gene

coding for such an AFP. A cooperative effect has been observed in AFPs from winter rye (Wai-Ching Hon *et al.*, *Plant Physiol.* 104:971-980, 1994) and from fish (Mulvihill *et al.*, *J. Biol. Chem.* 255:659-662, 1979; Osuga *et al.*, *J. Biol. Chem.* 235:6669-6672, 1978), indicating that the use of more than AFP of the present invention may be 5 beneficial. The polynucleotides of the present invention may also be employed in combination with other known sequences.

Techniques for stably incorporating genetic constructs into the genome of target organisms are well known in the art. Techniques for transforming plants include *Agrobacterium tumefaciens* mediated introduction, electroporation, protoplast fusion, 10 injection into reproductive organs, injection into immature embryos, high velocity projectile introduction and the like. The choice of technique will depend upon the target plant to be transformed. For example, dicotyledonous plants and certain monocots and gymnosperms may be transformed by *Agrobacterium* Ti plasmid technology, as described, for example by Bevan, *Nucleic Acid Res.* 12:8711-8721, 1984. Targets for 15 the introduction of the DNA constructs of the present invention include tissues, such as leaf tissue, disseminated cells, protoplasts, seeds, embryos, meristematic regions; cotyledons, hypocotyls, and the like. Transformation techniques which may be usefully employed in the inventive methods include those taught by Ellis *et al.*, *Plant Cell Reports*, 8:16-20, 1989, Wilson *et al.*, *Plant Cell Reports* 7:704-707, 1989, Tautorus *et* 20 *al.*, *Theor. Appl. Genet.* 78:531-536, 1989 and Ishida *et al.*, *Nat. Biotechnol.* 14:745-750, 1996.

Once the cells are transformed, cells having the inventive genetic construct incorporated in their genome may be selected by means of a marker, such as the kanamycin resistance marker discussed above. Transgenic cells may then be cultured in 25 an appropriate medium to regenerate whole organisms, such as plants, using techniques well known in the art. In the case of protoplasts, the cell wall is allowed to reform under appropriate osmotic conditions. In the case of seeds or embryos, an appropriate germination or callus initiation medium is employed. For explants, an appropriate regeneration medium is used. Regeneration of plants is well established for many 30 species. The resulting transformed plants may be reproduced sexually or asexually, using methods well known in the art, to give successive generations of transgenic plants.

Polypeptides of the present invention may be transiently expressed in target plants by means of viral vectors as described, for example by Fischer *et al.*, *Biotechnol.*

Appl. Biochem. 30:113-116, 1999. In such methods, a polynucleotide encoding the polypeptide of interest is cloned into the genome of a viral plant pathogen. The resulting infectious recombinant viral transcripts are used to infect plants and produce the polypeptide of interest. Techniques for employing recombinant plant viral vectors 5 to transiently express proteins in plants are well known in the art and include those disclosed in US Patent 6,369,296, the disclosure of which is hereby incorporated by reference. Introduction of the inventive AFPs using such viral vectors is particularly useful for frost protection of fruit trees, where transient expression of AFPs in frost sensitive parts of the trees, such as young floral/fruiting and leaf buds would be very 10 valuable.

Polynucleotides of the present invention may also be used to specifically suppress gene expression by methods that operate post-transcriptionally to block the synthesis of products of targeted genes, such as RNA interference (RNAi), and quelling. For a review of techniques of gene suppression see *Science*, 288:1370-1372, 15 2000. Exemplary gene silencing methods are also provided in WO 99/49029 and WO 99/53050. Posttranscriptional gene silencing is brought about by a sequence-specific RNA degradation process which results in the rapid degradation of transcripts of sequence-related genes. Studies have provided evidence that double-stranded RNA may act as a mediator of sequence-specific gene silencing (see, e.g., review by 20 Montgomery and Fire, *Trends in Genetics*, 14: 255-258, 1998). Gene constructs that produce transcripts with self-complementary regions are particularly efficient at gene silencing. A unique feature of this posttranscriptional gene silencing pathway is that silencing is not limited to the cells where it is initiated. The gene-silencing effects may be disseminated to other parts of an organism and even transmitted through the germ 25 line to several generations.

The polynucleotides of the present invention may be employed to generate gene silencing constructs and/or gene-specific self-complementary RNA sequences that can be delivered by conventional art-known methods to tissues, such as plant tissues. Within genetic constructs, sense and antisense sequences can be placed in regions 30 flanking an intron sequence in proper splicing orientation with donor and acceptor splicing sites, such that intron sequences are removed during processing of the transcript and sense and antisense sequences, as well as splice junction sequences, bind together to form double-stranded RNA. Alternatively, spacer sequences of various lengths may be employed to separate self-complementary regions of sequence in the

construct. During processing of the gene construct transcript, intron sequences are spliced-out, allowing sense and anti-sense sequences, as well as splice junction sequences, to bind forming double-stranded RNA. Select ribonucleases bind to and cleave the double-stranded RNA, thereby initiating the cascade of events leading to 5 degradation of specific mRNA gene sequences, and silencing specific genes. Alternatively, rather than using a gene construct to express the self-complementary RNA sequences, the gene-specific double-stranded RNA segments are delivered to one or more targeted areas to be internalized into the cell cytoplasm to exert a gene silencing effect. Gene silencing RNA sequences comprising the polynucleotides of the 10 present invention are useful for creating genetically modified plants with desired phenotypes as well as for characterizing genes (e.g., in high-throughput screening of sequences), and studying their functions in intact organisms.

In another embodiment, one or more of the inventive polypeptides may be employed in foliar applicants to protect target plants from damage due to low 15 temperatures and, in particular, from frost and/or freezing. Techniques for preparing and applying foliar applicants are well known and include those described in U.S. Patents 6,180,562 and 6,588,142. Preferably, foliar applicants comprising the inventive polypeptides are applied before early spring and early fall/autumn frosts in order to minimize damage to cold intolerant crops.

20 For use as foliar applicants, the inventive polypeptides may be formulated with known agricultural carriers, such as, but not limited to: water; alcohols; ketones; ethers; aliphatic hydrocarbons; aromatic hydrocarbons; sulfur-containing compounds; and powders of plant or animal origin, such as starch, activated carbon, calcium carbonate, talc, soybean flour, wheat flour. Such formulations may also, or alternatively, contain 25 an adjuvant, such as an extender, penetrant or surfactant. Extenders are adjuvants that can extend the useful life of a spray chemical, by increasing the chemical's adhesion to the leaf, by reducing any factor that can diminish chemical effectiveness, or by enhancing chemical weatherability. Some extenders have the ability to intercept ultraviolet light. Penetrants are adjuvants that help chemicals penetrate plants. 30 Surfactants are adjuvants that reduce the surface tensions of solutions, helping them spread and cover surfaces more effectively. Surfactants are probably the best-known class of adjuvants. Most adjuvants are a double-ended molecule, with one end being water soluble and one end being oil soluble. These molecules can therefore line-up between water-like compounds and oil-like compounds and make them more

compatible. Surfactants can be uncharged (non-ionic), positively charged (cationic), or negatively charged (anionic). Specific examples of these compounds include AgralTM, EthokemTM, Silwet-77TM, Sylgard 309TM, ActipronTM, CodacideTM, ActirobTM and the BrijTM series of compounds.

5 The resulting formulations may be in any form known in the art, such as liquids, dusts, granules, powders, emulsifiable concentrations, aerosols or pastes, and may be applied by conventional methods, such as spraying, jetting, misting, atomizing, soil application and surface application. The foliar applicants may also include additional components such as emulsifiers, suspending agents, dispersants, wetting agents, 10 thickeners and/or stabilizers, and may be used in combination with other active compounds, such as insecticides, herbicides and fungicides. The amount of polypeptide present within the foliar applicant will vary depending upon the formulation, manner and timing of application, condition of plants, and risk of frost or freeze damage. Preferably the polypeptide is present in a concentration of between 0.1 and 500,000 15 ppm, preferably between 1 and 100,000 ppm.

In another aspect, the present invention provides methods for using one or more of the inventive polypeptides or polynucleotides to treat disorders in a patient, preferably a mammal, more preferably a human. Disorders that may be treated using the inventive polypeptides and/or polynucleotides include those characterized by the 20 unwanted presence of biocrystals, such as gout and kidney stones.

In this aspect, the polypeptide or polynucleotide is generally present within a composition, such as a pharmaceutical or immunogenic composition. Pharmaceutical compositions may comprise one or more polypeptides, each of which may contain one or more of the above sequences (or variants thereof), and a physiologically acceptable 25 carrier. Immunogenic compositions may comprise one or more of the above polypeptides and an immunostimulant, such as an adjuvant or a liposome, into which the polypeptide is incorporated.

Alternatively, a composition of the present invention may contain DNA encoding one or more polypeptides described herein, such that the polypeptide is 30 generated *in situ*. In such compositions, the DNA may be present within any of a variety of delivery systems known to those of ordinary skill in the art, including nucleic acid expression systems, and bacterial and viral expression systems. Appropriate nucleic acid expression systems contain the necessary DNA sequences for expression in the patient (such as a suitable promoter and terminator signal). Bacterial delivery

systems involve the administration of a bacterium (such as *Bacillus Calmette-Guerin*) that expresses an immunogenic portion of the polypeptide on its cell surface. In a preferred embodiment, the DNA may be introduced using a viral expression system (e.g., vaccinia or other poxvirus, retrovirus, or adenovirus), which may involve the use 5 of a non-pathogenic, or defective, replication competent virus. Techniques for incorporating DNA into such expression systems are well known in the art. The DNA may also be "naked," as described, for example, in Ulmer *et al.*, *Science* 259:1745-1749, 1993 and reviewed by Cohen, *Science* 259:1691-1692, 1993. The uptake of naked DNA may be increased by coating the DNA onto biodegradable beads, 10 which are efficiently transported into the cells.

While any suitable carrier known to those of ordinary skill in the art may be employed in the pharmaceutical compositions of this invention, the type of carrier will vary depending on the mode of administration. For parenteral administration, such as subcutaneous injection, the carrier preferably comprises water, saline, alcohol, a lipid, a 15 wax or a buffer. For oral administration, any of the above carriers or a solid carrier, such as mannitol, lactose, starch, magnesium stearate, sodium saccharine, talcum, cellulose, glucose, sucrose, and magnesium carbonate, may be employed. Biodegradable microspheres (e.g., polylactic galactide) may also be employed as carriers for the pharmaceutical compositions of this invention. Suitable biodegradable 20 microspheres are disclosed, for example, in U.S. Patent Nos. 4,897,268 and 5,075,109.

Any of a variety of adjuvants may be employed in the immunogenic compositions of the present invention to non-specifically enhance an immune response. Most adjuvants contain a substance designed to protect the antigen from rapid catabolism, such as aluminum hydroxide or mineral oil, and a non-specific stimulator of 25 immune responses, such as lipid A, *Bordetella pertussis* or *M. tuberculosis*. Suitable adjuvants are commercially available as, for example, Freund's Incomplete Adjuvant and Freund's Complete Adjuvant (Difco Laboratories, Detroit, MI), and Merck Adjuvant 65 (Merck and Company, Inc., Rahway, NJ). Other suitable adjuvants include alum, biodegradable microspheres, monophosphoryl lipid A and Quil A.

30 Routes and frequency of administration of the inventive compositions, as well as dosage, vary from individual to individual. In general, the inventive compositions may be administered by injection (e.g., intradermal, intramuscular, intravenous or subcutaneous), intranasally (e.g., by aspiration) or orally. Preferably, the AFPs of the present invention are injected into the affected area or administered in a topical

application which is absorbed by the skin. In general, the amount of polypeptide present in a dose (or produced *in situ* by the DNA in a dose) ranges from about 1 pg to about 100 mg per kg of host, typically from about 10 pg to about 1 mg per kg of host, and preferably from about 100 pg to about 1 μ g per kg of host. Suitable dose sizes will 5 vary with the size of the patient, but will typically range from about 0.1 ml to about 2 ml.

Solutions comprising the inventive polypeptides may also be employed to improve the effectiveness of cryosurgery in, for example, the removal of unwanted tissue, such as tumor tissue. In such methods, the unwanted tissue is perfused with a 10 solution preferably comprising between 1mg/ml to about 30 mg/ml of the polypeptide. This can be accomplished, for example, by injection into the tissue, ingestion, or perfusion through the vasculature. Once the tissue is perfused with the polypeptide, cryoablation of the tissue is performed using a standard techniques employing, for example, a cryogenic probe. Cryogenic probes are preferably used in combination with 15 real-time imaging techniques, such as ultrasound and magnetic resonance imaging.

The inventive polypeptides and/or polynucleotides may also be employed as hydrate inhibitors in, for example, natural gas transmission lines. Gas hydrates form when water molecules crystallize around natural gas guest molecules. This co-crystallization process, which has been recognized for several years, is well 20 characterized and occurs with the right combination of temperature and pressure. Gas hydrates may form in any place where water coexists with natural gas at temperatures as high as 80° F. Long gas transmission lines are particularly vulnerable to hydrate blockage during extended cold weather periods. Sub-sea pipelines may have hydrate problems continually due to the cooling effect of seawater at depth. While there are a 25 few known methods of preventing hydrate formation, thermodynamic solutions such as removing the water, heating the system and lowering the pressure, are often not practical. Another thermodynamic method, the addition of sufficient amounts of ethylene glycol or methanol to decrease hydrate stability, effectively lowers the temperature of hydrate formation. This method requires relatively large amounts of 30 ethylene glycol or methanol, which are inconvenient to use and hazardous due to both chemical toxicity and flammability. This method of treatment can also be quite expensive. Use of the inventive AFPs would be a safer alternative to the use of ethylene glycol and/or methanol

Another application of the inventive AFPs is in any spraying process which uses a solution (containing water) at freezing temperatures. One or more of the inventive AFPs could be employed as an anti-clogging agent, by reducing the size of ice crystal to provide a reduced frequency of blocking in the spraying nozzles. This effect might also 5 be applied in the sugar industry where a solution of sugar is sprayed to crystallize and dry it. AFPs could be employed to prevent clogging of the nozzles by reducing and controlling crystal size, with at the same time having the added benefit of reducing drying time.

10 The following examples are offered by way of illustration and not by way of limitation.

Example 1ISOLATION OF cDNA SEQUENCES FROM *L. PERENNE* AND
F. ARUNDINACEA cDNA LIBRARIES

5 *L. perenne* and *F. arundinacea* cDNA expression libraries were constructed and screened as follows. Tissue was collected from *L. perenne* and *F. arundinacea* during winter and spring, and snap-frozen in liquid nitrogen. The tissues collected include those obtained from leaf blades, leaf base, pseudostem, roots and stem. Total RNA was isolated from each tissue type using TRIzol Reagent (BRL Life Technologies, 10 Gaithersburg, MD). mRNA from each tissue type was obtained using a Poly(A) Quik mRNA isolation kit (Stratagene, La Jolla, CA), according to the manufacturer's specifications. cDNA expression libraries were constructed from the purified mRNA by reverse transcriptase synthesis followed by insertion of the resulting cDNA in Lambda ZAP using a ZAP Express cDNA Synthesis Kit (Stratagene), according to the 15 manufacturer's protocol. The resulting cDNA clones were packaged using a Gigapack II Packaging Extract (Stratagene) employing 1 µl of sample DNA from the 5 µl ligation mix. Mass excision of the libraries was done using XL1-Blue MRF' cells and XLORL cells (Stratagene) with ExAssist helper phage (Stratagene). The excised phagemids were diluted with NZY broth (Gibco BRL, Gaithersburg, MD) and plated out onto 20 LB-kanamycin agar plates containing 5-bromo-4-chloro-3-indolyl-beta-D-galactosidase (X-gal) and isopropylthio-beta-galactoside (IPTG).

Of the colonies plated and picked for DNA preparations, the large majority contained an insert suitable for sequencing. Positive colonies were cultured in NZY broth with kanamycin and DNA was purified following standard protocols. Agarose 25 gel at 1% was used to screen sequencing templates for chromosomal contamination. Dye terminator sequences were prepared using a Biomek 2000 robot (Beckman Coulter Inc., Fullerton, CA) for liquid handling and DNA amplification using a 9700 PCR machine (Perkin Elmer/Applied Biosystems, Foster City, CA) according to the manufacturer's protocol.

30 The DNA sequences for positive clones were obtained using a Perkin Elmer/Applied Biosystems Division Prism 377 sequencer. cDNA clones were sequenced from the 5' end. The polynucleotide sequences identified as SEQ ID NOS: 3 and 10 were identified from *L. perenne* leaf blade cDNA expression libraries; the polynucleotide sequences identified as SEQ ID NOS: 8 and 12 were identified from *L.*

perenne leaf and pseudostem cDNA expression libraries; the polynucleotide sequence identified as SEQ ID NO: 1 was identified from *L. perenne* pseudostem cDNA expression libraries; the polynucleotide sequences identified as SEQ ID NOS: 5, 6 and 25 were identified from a *L. perenne* root cDNA expression library; the polynucleotide 5 sequences identified as SEQ ID NOS: 4, 7, 9 and 11 were identified from *F. arundinacea* leaf blade cDNA expression libraries; and the polynucleotide sequence identified as SEQ ID NO: 2 was identified from *F. arundinacea* basal stem cDNA expression libraries. All of the sequences of SEQ ID NO: 1-12 are believed to be full-length. The amino acid sequences corresponding to the cDNA sequences of SEQ ID 10 NO: 1-12 and 25 are provided in SEQ ID NO: 13-24 and 26, respectively.

BLASTN Polynucleotide Analysis

The isolated cDNA sequences were compared to sequences in the EMBL DNA database using the computer algorithm BLASTN. Comparisons of DNA sequences 15 provided in SEQ ID NOS: 1-12 to sequences in the EMBL DNA database were made as of August 23, 2002, using BLASTN algorithm Version 2.0.11 [Jan-20-2000] and the following Unix running command: blastall -p blastn -d embldb -e 10 -G0 -E0 -FF -r 1 -v 30 -b 30 -i queryseq -o. Comparisons of the DNA sequence provided in SEQ ID NO: 25 to sequences in the EMBL DNA database were made as of August 15, 2003, 20 using BLASTN algorithm Version 2.0.11 [Jan-20-2000] and the same Unix running command.

The sequences of SEQ ID NOS: 1-12 and 25 were determined to have less than 50% identity to sequences in the EMBL database using the computer algorithm BLASTN, as described above.

25

BLASTP Polypeptide Analysis

Comparisons of protein sequences provided in SEQ ID NOS: 13-24, to sequences in the SwissProt- TrEMBLE protein database were made as of August 23, 2002 using BLASTP algorithm Version 2.0.11 [Jan-20-2000], and the following Unix 30 running command: blastall -p blastp -d swissprottrembledb -e 10 -G0 -E0 -FF -v 30 -b 30 -i queryseq -o. Comparison of the protein sequence provided in SEQ ID NO: 26 to sequences in the SwissProt-TrEMBLE protein database were made as of August 15, 2003 using BLASTP algorithm Version 2.0.11 [Jan-20-2000] and the same Unix running command.

The sequences of SEQ ID NOS: 13-24 and 26 were determined to have less than 50% identity to sequences in the SwissProt-TrEMBLE database determined as described above using the computer algorithm BLASTP.

5 BLASTX Polynucleotide Analysis

Comparisons of DNA sequences provided in SEQ ID NOS: 1-12, to sequences in the SwissProt-TrEMBLE protein database (using BLASTX) were made as of August 23, 2002 using BLAST algorithm Version 2.0.11 [Jan-20-2000], and the following Unix running command: blastall -p blastx -d swissprottrembledb -e 10 -G0 -E0 -FF 10 -v 30 -b 30 -i queryseq -o. Comparison of the DNA sequence provided in SEQ ID NO: 25 to sequences in the SwissProt-TrEMBLE protein database (using BLASTX) were made as of August 15, 2003 using BLAST algorithm Version 2.0.11 [Jan-20-2000] and the same Unix running command.

The sequences of SEQ ID NOS: 1-12 and 25 were determined to have less than 15 50% identity to sequences in the SwissProt-TrEMBLE database, determined as described above using the computer algorithm BLASTX.

The location of open reading frames (ORFs), by nucleotide position, contained within the sequences of SEQ ID NO: 1-12 and 25, and the corresponding amino acid sequences are provided in Table 2 below.

20

Example 2USE OF GRASS ANTI-FREEZE PROTEIN GENES TO ALTER ICE CRYSTAL STRUCTURETransformation of *Arabidopsis* plants with grass anti-freeze protein genes

5 Sense constructs containing a polynucleotide including the coding region of AFP genes isolated from *Lolium perenne* or *Festuca arundinacea* (SEQ ID NOS: 1, 3, 5, 8 and 10) were inserted into a binary vector and used to transform *Agrobacterium tumefaciens* LBA4404 using published methods (see, An G, Ebert PR, Mitra A, Ha SB, "Binary Vectors," in Gelvin SB, Schilperoort RA, eds., *Plant Molecular Biology* 10 *Manual*, Kluwer Academic Publishers: Dordrecht, 1988). The presence and integrity of the binary vector in *A. tumefaciens* was verified by the polymerase chain reaction (PCR) using vector primers.

The *A. tumefaciens* containing the sense gene constructs were used to transform *Arabidopsis*, by floral dipping (Clough and Bent, *Plant J.* 16:735-743, 1998). Several 15 independent transformed plant lines were established for the sense construct for each gene. Transformed plants were allowed to self fertilize and T1 seed collected. A number of T2 plants from each original T1 plant were tested to confirm the presence of the appropriate anti-freeze gene construct by PCR analysis of genomic DNA. The primers listed in SEQ ID NOS: 27 and 28 were used for AFP1 (SEQ ID NO: 1), the 20 primers listed in SEQ ID NOS: 29 and 30 were used for AFP2 (SEQ ID NO: 3), the primers listed in SEQ ID NOS: 31 and 32 were used for AFP4 (SEQ ID NO: 8), and the primers listed in SEQ ID NOS: 33 and 34 were used for AFP5 (SEQ ID NO: 10). No transgene was seen in the empty-vector transformed control plants.

25 Increased freezing tolerance of the AFP-expressing plants

Plants are tested for increased survival after enduring freezing conditions, in comparison to wild type empty vector control *Arabidopsis*. A plate-based assay is employed, similar to previous assays that tested *Arabidopsis* mutants for changes in freezing tolerance (Chinnusamy *et al.*, *Genes Dev.* 17:1043-1054, 2003). Briefly, 90 30 T2 seedlings of each line, 10 independent transgenic lines per construct, are sown on to MS plus sucrose agar plates. The seed is stratified at 4°C for 2 days before germinating at 22°C for 10 days, followed by a 4 day cold acclimation at 4°C, low light. The seedlings are then subjected to a freezing cycle in a controlled environment unit. Plates are incubated at -1°C for 16 hours and sprinkled with ice chips to attain even freezing.

The temperature is lowered at 1°C per hour to either -10°C or -12°C and the minimum temperature is maintained for 2 hours before placing the plants at 4°C for 12 hours to thaw. The plants are then kept at 22°C and visually scored for survival after 2 days.

5

Example 3USE OF GRASS ANTI-FREEZE PROTEIN GENES TO CHANGE ICE CRYSTAL SIZE

A number of grass anti-freeze protein genes (SEQ ID NOS: 1, 3, 5, and 11), as well as a truncated gene derived from AFP1 (SEQ ID NO: 1), were expressed in 10 *Escherichia coli* and purified using standard protocols. The grass genes were amplified by PCR using the forward and reverse primers listed in SEQ ID NOS: 35 and 36 for AFP1 (SEQ ID NO: 1), SEQ ID NOS: 39 and 40 for AFP2 (SEQ ID NO: 3), SEQ ID NOS: 41 and 42 for AFP3 (SEQ ID NO: 5), and SEQ ID NOS: 43 and 44 for AFP5 (SEQ ID NO: 11). The truncated AFP1 gene was amplified using the primers given in 15 SEQ ID NOS: 37 and 38. The resulting fragments were cloned into a modified pET16b expression plasmid (six histidines followed by an *Eco*RI site then the *Bam*HI site) in frame with the histidine Tag sequence. The resulting plasmids were transformed into *Escherichia coli* BL21 cells using standard protocols and protein expression induced using IPTG. The insoluble recombinant proteins in the form of inclusion bodies were 20 extracted from bacterial cells by multi-phase sonication in a buffer consisting of 2M urea, 20 mM Tris-HCl, 0.5 M NaCl and 2 % Triton X-100 at a pH of 8.0. The resulting proteins were solubilized over the course of one hour in a buffer consisting of 6 M guanidinium hydrochloride, 20 mM Tris-HCl, 0.5 M NaCl, 10 mM imidazole and 1 mM 2-mercaptoethanol at a pH of 8.0. Target proteins were purified by His Tag 25 binding affinity chromatography on Chelating Sepharose Fast Flow columns, previously charged with NiSO₄. A one hour linear gradient of 6 M to 0 M urea, at a flow rate of 0.4 ml/ min was used to refold the target proteins on the affinity matrix. Elution using a buffer containing 20 mM Tris-HCl, 0.5 M NaCl, 0.5 M imidazole and 1 mM 2-mercaptoethanol at a pH of 8.0 followed this. Eluted material was subjected to 30 electrophoresis on a 4-12 % NuPAGE gel and visualised by staining using Coomassie Brilliant Blue. Intensely stained purified bands were identified for protein genes SEQ ID NO: 1, 3, 5 and 11. These were further confirmed by trypsin digestion of soluble protein fractions or protein gel band isolation followed by mass spectrometry.

Digested fragments were compared to the Mass Spectrometry Data Base (MSDB) where proteins encoded by the DNA sequences of SEQ ID NO: 3, 5 and 11 (amino acid sequences provided in SEQ ID NO: 15, 17 and 23, respectively) were positively identified. The protein gene product of SEQ ID NO: 1 (amino acid sequence 5 provided in SEQ ID NO: 13) was identified by comparison to a limited in-house database. Proteins with SEQ ID NO: 15, 17 and 23 were dialyzed against 20 mM Tris-HCl at pH 8.0. In addition, proteins with SEQ ID NO: 13, 15, 17 and 23 were also maintained in their elution state *i.e.* in a buffer containing 20 mM Tris-HCl, 0.5 M NaCl, 0.5 M imidazole and 1 mM 2-mercaptoethanol at a pH of 8.0.

10 The purified protein of SEQ ID NO: 23, encoded by SEQ ID NO: 11, was tested in the "SPLAT" assay (Smallwood *et al.*, *Biochem. J.* 340:385-391, 1999) to investigate its impact on ice restructuring. In the sucrose-sandwich-splat assay, 2 μ l of purified protein in 30% (w/w) sucrose was squashed between 13 mm circular cover slips. The 'sandwich' was dropped into a bath of heptane held at -80 °C in a box of solid CO₂ and 15 transferred into a glass viewing chamber containing heptane maintained at -6°C by a circulating cooler (Grant). Ice crystals were viewed using a 20x objective on an Optiphot microscope (Nikon) and images captured at 0 and 30 minutes incubation at -6°C using a video camera into an image analysis system (LUCIA, Nikon). The results showed that antifreeze protein AFP5, corresponding to the product from SEQ ID NO: 20 11, inhibited ice recrystallization at a concentration of 0.9 and 1.8 mg/ml. The effects could clearly be observed at the initiation of the assay *i.e.* time = zero minutes, but were far more pronounced at the thirty-minute interval. At this point the ice crystals formed using the 20 mM Tris-HCl control were many fold larger than the ice crystals formed in 25 the presence of AFP5 at either 0.5 or 1.0 mg/ml. AFP5 also displayed a concentration effect where the ice crystals formed at the higher concentration were smaller than those that propagated at the lower concentration.

As the SPLAT assay is performed in 30% sucrose, these results also showed that AFP5 is able to modify sucrose solutions.

Example 4

USE OF GRASS ANTI-FREEZE PROTEIN GENES TO REDUCE DRYING TIME

Antifreeze proteins AFP2, AFP3 and AFP5 corresponding to the products from 5 SEQ ID NOS: 3, 5 and 11 (amino acid sequences provided in SEQ ID NO: 15, 17 and 23, respectively) were tested for their ability to increase the rate of drying of liquids in a SpeedVacTM vacuum concentrator set at medium heat. After dialysis against 20 mM Tris-HCl pH 8.0, the concentration of Tris-HCl was adjusted to 8 mM. AFPs in Tris buffer were pipetted into 1.5 ml eppendorf tubes such that each tube contained 500 µl of 10 liquid. Antifreeze proteins were in the range of 0.1 µg to 200 µg in 500 µl volumes. Controls of either 500 µl 8 mM Tris or 500 µl MilliQ water were used. AFP2 and AFP3, at a concentration of 20 to 100 µg/ml facilitated rapid drying of 500 µl of 8 mM Tris-HCl in 75 minutes. Controls remained at volumes of 200-300 µl after 4 hours of 15 vacuum drying. AFP5 at a concentration of between 100 and 400 µg/ml reduced in volume to approximately 20-50 µl after 4 hours. This compared favorably to controls, which had volumes of 200-300 µl after 4 hours. These results demonstrate that AFPs used as additives reduced the drying time significantly.

20 SEQ ID NOS: 1-44 are set out in the attached Sequence Listing. The codes for nucleotide sequences used in the attached Sequence Listing, including the symbol "n," conform to WIPO Standard ST.25 (1998), Appendix 2, Table 1.

All references cited herein, including patent references and non-patent publications, are hereby incorporated by reference in their entireties.

25 While in the foregoing specification this invention has been described in relation to certain preferred embodiments, and many details have been set forth for purposes of illustration, it will be apparent to those skilled in the art that the invention is susceptible to additional embodiments and that certain of the details described herein may be varied considerably without departing from the basic principles of the invention.

Claims

We claim:

1. An isolated polynucleotide comprising a sequence selected from the group consisting of: SEQ ID NO: 1-12 and 25.
2. An isolated polynucleotide comprising a sequence selected from the group consisting of:
 - (a) complements of SEQ ID NO: 1-12 and 25;
 - (b) reverse complements of SEQ ID NO: 1-12 and 25;
 - (c) reverse sequences of SEQ ID NO: 1-12 and 25;
 - (d) sequences that are 100-mers of a sequence of SEQ ID NO: 1-12 and 25;
 - (e) sequences that are 40-mers of a sequence of SEQ ID NO: 1-12 and 25; and
 - (f) sequences that are 20-mers of a sequence of SEQ ID NO: 1-12 and 25.
3. An isolated polynucleotide comprising a sequence selected from the group consisting of:
 - (a) sequences having at least 75% identity to a sequence of SEQ ID NO: 1-12 and 25;
 - (b) sequences having at least 90% identity to a sequence of SEQ ID NO: 1-12 and 25;
 - (c) sequences having at least 95% identity to a sequence of SEQ ID NO: 1-12 and 25;
 - (d) sequences having at least 98% identity to a sequence of SEQ ID NO: 1-12 and 25; and
 - (e) sequences that hybridize to a sequence of SEQ ID NO: 1-12 and 25 under stringent hybridization conditions,
wherein the polynucleotide encodes a polypeptide having substantially the same functional properties as a polypeptide encoded by SEQ ID NO: 1-12 or 25.
4. An isolated oligonucleotide probe or primer comprising at least 10 contiguous residues complementary to 10 contiguous residues of a nucleotide sequence recited in claim 1.
5. A kit comprising a plurality of oligonucleotide probes or primers of claim 4.

6. An isolated polypeptide encoded by a polynucleotide of claim 1.
7. An isolated polypeptide comprising an amino acid sequence selected from the group consisting of: sequences recited in SEQ ID NO: 13-24 and 26.
8. The isolated polypeptide of claim 7, wherein the polypeptide is in multimeric form.
9. An isolated polypeptide comprising an amino acid sequence selected from the group consisting of:
 - (a) sequences having at least 75% identity to a sequence of SEQ ID NO: 13-24 and 26;
 - (b) sequences having at least 90% identity to a sequence of SEQ ID NO: 13-24 and 26;
 - (c) sequences having at least 95% identity to a sequence of SEQ ID NO: 13-24 and 26;
 - (d) sequences having at least 98% identity to a sequence of SEQ ID NO: 13-24; and
 - (e) functional portions of a sequence of SEQ ID NO: 13-24 and 26,wherein the polypeptide possesses an ability to bind ice crystals.
10. An isolated polynucleotide that encodes a polypeptide of any one of claims 7-9.
11. A genetic construct comprising a polynucleotide of any one of claims 1-3.
12. A transgenic cell comprising a genetic construct according to claim 11.
13. A genetic construct comprising, in the 5'-3' direction:
 - (a) a gene promoter sequence;
 - (b) a polynucleotide sequence comprising at least one of the following: (1) a polynucleotide coding for at least a functional portion of a polypeptide encoded by a polynucleotide of any one of claims 1-3; and (2) a

polynucleotide comprising a non-coding region of a polynucleotide of any one of claims 1-3; and

(c) a gene termination sequence.

14. The genetic construct of claim 13 wherein the polynucleotide is in a sense orientation.

15. The genetic construct of claim 13 wherein the polynucleotide is in an anti-sense orientation.

16. A transgenic cell comprising a genetic construct of claim 13.

17. An organism comprising a transgenic cell according to claim 16, or progeny thereof.

18. A method for modulating cold tolerance in an organism, comprising stably incorporating into the genome of the organism at least one polynucleotide of any one of claims 1-3.

19. The method of claim 18, wherein the organism is selected from the group consisting of: plants; mammals; insects; fungi; archaea; and bacteria.

20. The method of claim 18, comprising stably incorporating into the genome of the organism a genetic construct of claim 13.

21. A method for producing a plant having altered cold tolerance, comprising:

(a) transforming a plant cell with a genetic construct of claim 13 to provide a transgenic cell; and

(b) cultivating the transgenic cell under conditions conducive to regeneration and mature plant growth.

22. The method of claim 21 wherein the plant is selected from the group consisting of: *Lolium* species; *Festuca* species; and *Eucalyptus* species.

23. A method for modifying the activity of an antifreeze protein in an organism comprising stably incorporating into the genome of the organism a genetic construct of claim 13.
24. A method for modifying the activity of an antifreeze protein in an organism, comprising introducing into cells of the organism double stranded RNA corresponding to a polynucleotide of any one of claims 1-3, thereby inhibiting expression of a polypeptide encoded by the polynucleotide.
25. A method for cryopreserving a cell or tissue, comprising contacting the cell or tissue with at least one polypeptide of any one of claims 7-9.
26. A food additive comprising a polypeptide of any one of claims 7-9.
27. A frozen food product comprising a food additive of claim 25.
28. A method for decreasing an amount of time required to dehydrate a composition comprising contacting the composition with a polypeptide of any one of claims 7-9.
29. A composition comprising a polypeptide of any one of claims 7-9 and a physiologically acceptable carrier.
30. A method for the treatment of a disorder characterized by the presence of unwanted biocrystals in a patient, comprising administering to the patient a composition of claim 29.
31. A method for preserving the viability of a molecular biology reagent, comprising contacting the reagent with a polypeptide of any one of claims 7-9.
32. A method for destroying unwanted tissue in a patient, comprising:
 - (a) perfusing the tissue with a solution comprising a polypeptide of any one of claims 7-9; and
 - (b) freezing the tissue for a period of time sufficient to mortally damage cells within the tissue.

33. The method of claim 32, wherein the undesirable tissue is tumor tissue.
34. A composition comprising at least one polypeptide of any one of claims 7-9 and an agricultural carrier.
35. A method for protecting a plant from damage due to frost or freezing, comprising applying a composition of claim 34 to the plant.

SEQUENCE LISTING

<110> Demmer, Jeroen
 Shenk, Michael Andrew
 Hall, Claire
 Fish, Steven A

<120> Compositions isolated from forage
 grasses and methods for their use.

WO 2004/022700 A3

(54) Title: ANTIFREEZE PROTEINS ISOLATED FROM FORAGE GRASSES AND METHODS FOR THEIR USE

(57) Abstract: Isolated polynucleotides encoding antifreeze polypeptides are provided, together with expression vectors and host cells comprising such isolated polynucleotides. Methods for the use of such polynucleotides and polypeptides are also provided.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/NZ2003/000199

Box I Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. Claims Nos :
because they relate to subject matter not required to be searched by this Authority, namely:

2. Claims Nos :
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. Claims Nos :
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a)

Box II Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

The ISA found 13 separate inventions.

See Supplemental Box II for details

1. As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims
2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by Sequence Id Nos: 1-8, 10 and 13-20, 22 and 24.

Remark on Protest

The additional search fees were accompanied by the applicant's protest.

No protest accompanied the payment of additional search fees.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/NZ2003/000199

Supplemental Box II

(To be used when the space in any of Boxes I to VIII is not sufficient)

Continuation of Box No: II

Lack Of Unity

It is a requirement of the PCT, under rule 13 of the PCT, that the claims shall define a single invention, where all claims are linked by a common special technical feature that defines the invention. A special technical feature is defined as being that feature that provides the advance over the prior art. The present claims do not conform to this requirement.

The ISA has identified 13 separate inventions.

The present claims are directed to 13 proteins and their encoding nucleic acids that have been isolated from either perennial ryegrass or tall fescue, whose common feature is that they are antifreeze proteins. Plant antifreeze proteins, including those from grasses, are known. Thus the common feature of plant, or more specifically grass, antifreeze protein activity cannot be a special technical feature that unites the proteins of the claims. Thus each protein and its encoding nucleic acid of the claims defines a single invention.

As a service to the Applicants, 10 amino acid sequences, and their encoding polynucleotide sequences, as specified by the applicants, have been searched.

INTERNATIONAL SEARCH REPORT

Information on patent family members

International application No.

PCT/NZ2003/000199

This Annex lists the known "A" publication level patent family members relating to the patent documents cited in the above-mentioned international search report. The Australian Patent Office is in no way liable for these particulars which are merely given for the purpose of information.
